ABSTRACT

Background
Pressure ulcers (also known as pressure injuries, pressure sores, decubitus ulcers and bed sores) are localised injuries to the skin or underlying soft tissue, or both, caused by unrelieved pressure, shear or friction. Reactive air surfaces (beds, mattresses or overlays) can be used for preventing pressure ulcers.

Objectives
To assess the effects of reactive air beds, mattresses or overlays compared with any support surface on the incidence of pressure ulcers in any population in any setting.

Search methods
In November 2019, we searched the Cochrane Wounds Specialised Register; the Cochrane Central Register of Controlled Trials (CENTRAL); Ovid MEDLINE (including In-Process & Other Non-Indexed Citations); Ovid Embase and EBSCO CINAHL Plus. We also searched clinical trials registries for ongoing and unpublished studies, and scanned reference lists of relevant included studies as well as reviews, meta-analyses and health technology reports to identify additional studies. There were no restrictions with respect to language, date of publication or study setting.

Selection criteria
We included randomised controlled trials that allocated participants of any age to reactive air beds, overlays or mattresses. Comparators were any beds, overlays or mattresses that were applied for preventing pressure ulcers.

Data collection and analysis
At least two review authors independently assessed studies using predetermined inclusion criteria. We carried out data extraction, ‘Risk of bias’ assessment using the Cochrane ‘Risk of bias’ tool, and the certainty of the evidence assessment according to Grading of Recommendations, Assessment, Development and Evaluations methodology. If a reactive air surface was compared with surfaces that were not clearly specified, then we recorded and described the concerned study but did not included it in further data analyses.
Main results

We included 17 studies (2604 participants) in this review. Most studies were small (median study sample size: 83 participants). The average participant age ranged from 56 to 87 years (median: 72 years). Participants were recruited from a wide range of care settings with the majority being acute care settings. Almost all studies were conducted in the regions of Europe and America. Of the 17 included studies, two (223 participants) compared reactive air surfaces with surfaces that were not well described and therefore could not be classified. We analysed data for five comparisons: reactive air surfaces compared with (1) alternating pressure (active) air surfaces (seven studies with 1728 participants), (2) foam surfaces (four studies with 229 participants), (3) reactive water surfaces (one study with 37 participants), (4) reactive gel surfaces (one study with 66 participants), and (5) another type of reactive air surface (two studies with 223 participants). Of the 17 studies, seven (41.2%) presented findings which were considered at high overall risk of bias.

Primary outcome: Pressure ulcer incidence

Reactive air surfaces may reduce the proportion of participants developing a new pressure ulcer compared with foam surfaces (risk ratio (RR) 0.42; 95% confidence interval (CI) 0.18 to 0.96; I² = 25%; 4 studies, 229 participants; low-certainty evidence). It is uncertain if there is a difference in the proportions of participants developing a new pressure ulcer on reactive air surfaces compared with: alternating pressure (active) air surfaces (6 studies, 1648 participants); reactive water surfaces (1 study, 37 participants); reactive gel surfaces (1 study, 66 participants), or another type of reactive air surface (2 studies, 223 participants). Evidence for all these comparisons is of very low certainty.

Included studies have data on time to pressure ulcer incidence for two comparisons. When time to pressure ulcer incidence is considered using a hazard ratio (HR), low-certainty evidence suggests that in the nursing home setting, people on reactive air surfaces may be less likely to develop a new pressure ulcer over 14 days’ of follow-up than people on alternating pressure (active) air surfaces (HR 0.44; 95% CI 0.21 to 0.96; 1 study, 308 participants). It is uncertain if there is a difference in the hazard of developing new pressure ulcers between two types of reactive air surfaces (1 study, 123 participants; very low-certainty evidence).

Secondary outcomes

Support-surface-associated patient comfort: the included studies have data on this outcome for three comparisons. We could not pool any data as comfort outcome measures differed between included studies; therefore a narrative summary is provided. It is uncertain if there is a difference in patient comfort responses between reactive air surfaces and foam surfaces over the top of an alternating pressure (active) air surfaces (1 study, 72 participants), and between those using reactive air surfaces and those using alternating pressure (active) air surfaces (4 studies, 1364 participants). Evidence for these two comparisons is of very low certainty. It is also uncertain if there is a difference in patient comfort responses between two types of reactive air surfaces (1 study, 84 participants; low-certainty evidence).

All reported adverse events: there were data on this outcome for one comparison: it is uncertain if there is a difference in adverse events between reactive air surfaces and foam surfaces (1 study, 72 participants; very low-certainty evidence).

The included studies have no data for health-related quality of life and cost-effectiveness for all five comparisons.

Authors’ conclusions

Current evidence is uncertain regarding any differences in the relative effects of reactive air surfaces on ulcer incidence and patient comfort, when compared with reactive water surfaces, reactive gel surfaces, or another type of reactive air surface. Using reactive air surfaces may reduce the risk of developing new pressure ulcers compared with using foam surfaces. Also, using reactive air surfaces may reduce the risk of developing new pressure ulcers within 14 days compared with alternating pressure (active) air surfaces in people in a nursing home setting.

Future research in this area should consider evaluation of the most important support surfaces from the perspective of decision-makers. Time-to-event outcomes, careful assessment of adverse events and trial-level cost-effectiveness evaluation should be considered in future studies. Trials should be designed to minimise the risk of detection bias; for example, by using digital photography and adjudicators of the photographs being blinded to group allocation. Further review using network meta-analysis will add to the findings reported here.

PLAIN LANGUAGE SUMMARY

Do beds, mattresses and mattress toppers with air-filled surfaces that apply constant pressure to the skin prevent pressure ulcers?

Key messages

Reactive, air-filled surfaces that apply constant pressure to the skin may reduce people’s chances of developing pressure ulcers compared with foam surfaces.

They may also be better at preventing pressure ulcers among people in nursing homes than air-filled surfaces that regularly redistribute pressure under the body.
More research is needed to strengthen the evidence. Future studies should focus on options and effects that are important to decision-makers, such as:

- Reactive, air-filled surfaces that apply constant skin pressure, compared with air-filled surfaces that regularly redistribute pressure; and
- whether and when pressure ulcers develop, unwanted effects and costs.

**What are pressure ulcers?**

Pressure ulcers are also known as pressure sores or bed sores. They are wounds to the skin and underlying tissue caused by prolonged pressure or rubbing. They often occur on bony parts of the body, such as heels, elbows, hips and the bottom of the spine. People who have mobility problems or who lie in bed for long periods are at risk of developing pressure ulcers.

**What did we want to find out?**

There are beds, mattresses and mattress toppers specifically designed for people at risk of pressure ulcers. These can be made of a range of materials (such as foam, air cells or water bags) and are divided into two groups:

- reactive (static) surfaces that apply a constant pressure to the skin, unless a person moves or is repositioned; and
- active (alternating pressure) surfaces that regularly redistribute the pressure under the body.

We wanted to find out if reactive, air-filled surfaces:

- prevent pressure ulcers;
- are comfortable and improve people’s quality of life;
- have health benefits that outweigh their costs; and
- have any unwanted effects.

**What did we do?**

We searched the medical literature for studies that evaluated the effects of beds, mattresses and mattress toppers with a reactive, air-filled surface. We compared and summarised their results, and rated our confidence in the evidence, based on factors such as study methods and sizes.

**What did we find?**

We found 17 studies (2604 people, average age: 72 years) that lasted between five days and six months (average: 14 days). The studies compared reactive, air-filled surfaces with:

- foam surfaces;
- active, air-filled surfaces; and
- reactive surfaces filled with water, gel or other materials.

**Pressure ulcer prevention**

The evidence suggests that fewer people may develop pressure ulcers when lying on a reactive, air-filled surface compared with:

- foam surfaces (four studies, 229 people); and
- an active, air-filled surface (one study, 308 people in a nursing home, followed for 14 days).

It is unclear whether reactive, air-filled surfaces prevent ulcers more than other types of reactive surfaces.

**Other effects**

The studies did not provide sufficiently robust and clear evidence for us to determine how reactive, air-filled surfaces affect comfort and unwanted effects. No studies reported information about quality of life and cost.

**What limited our confidence in the evidence?**

Most studies were small (83 people on average). Seven studies used methods likely to introduce errors in their results. It was unclear whether the other 10 studies used robust methods.
How up-to-date is this review?

The evidence in this Cochrane Review is current to November 2019.
### SUMMARY OF FINDINGS

*Anticipated absolute effects calculated using: Risk with alternating pressure (active) air surfaces - Risk with reactive air surfaces.
The risk in the intervention group (and its 95% confidence interval) is based on the assumed risk in the comparison group and the relative effect of the intervention (and its 95% CI).

CI: Confidence interval; RR: Risk ratio; HR: Hazard ratio

GRADE Working Group grades of evidence

High certainty: we are very confident that the true effect lies close to that of the estimate of the effect.
Moderate certainty: we are moderately confident in the effect estimate; the true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different.
Low certainty: our confidence in the effect estimate is limited; the true effect may be substantially different from the estimate of the effect.
Very low certainty: we have very little confidence in the effect estimate; the true effect is likely to be substantially different from the estimate of effect.

a) Downgraded twice for high risk of bias in domains other than performance bias for four studies contributing over 54% weight in the meta-analysis.
b) Downgraded once for imprecision as, despite the fact that the optimal information size (OIS) was met, the confidence interval was wide and crossed RR = 0.75.
c) Downgraded twice for high risk of detection bias.
d) Downgraded once for high overall risk of bias in 3 small studies but unclear risk of bias in 1 large study.
e) Downgraded twice for substantial inconsistency.

GRADE Working Group grades of evidence

High certainty: we are very confident that the true effect lies close to that of the estimate of the effect.

Moderate certainty: we are moderately confident in the effect estimate; the true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different.

Low certainty: our confidence in the effect estimate is limited; the true effect may be substantially different from the estimate of the effect.

Very low certainty: we have very little confidence in the effect estimate; the true effect is likely to be substantially different from the estimate of the effect.

Downgraded once for unclear overall risk of bias.

Downgraded twice for imprecision because the OS was not met and the confidence interval was very wide and crossed RRs = 0.75 and 1.25.
Description of the condition

Pressure ulcers — also known as pressure injuries, pressure sores, decubitus ulcers and bed sores — are localised injuries to the skin or underlying soft tissue (or both) caused by unrelieved pressure, shear or friction (NPIAP 2016). Pressure ulcer severity is generally classified as follows, using the National Pressure Injury Advisory Panel (NPIAP) system (NPIAP 2016).

- Stage 1: intact skin with a local appearance of non-blanchable erythema
- Stage 2: partial-thickness skin loss with exposed dermis
- Stage 3: full-thickness skin loss
- Stage 4: full-thickness skin and tissue loss with visible fascia, muscle, tendon, ligament, cartilage or bone
- Unstageable pressure injury: full-thickness skin and tissue loss that is obscured by slough or eschar so that the severity of injury cannot be confirmed
- Deep tissue pressure injury: local injury of persistent, non-blanchable deep red, maroon, purple discolouration or epidermal separation revealing a dark wound bed or blood-filled blister

The stages described above are consistent with those described in another commonly used system, the International Classification of Diseases for Mortality and Morbidity Statistics (World Health Organization 2019).

Pressure ulcers are complex wounds that are relatively common, affecting people across different care settings. A systematic review found that prevalence estimates for people affected by pressure ulcers in communities of the UK, USA, Ireland and Sweden ranged from 5.6 to 23.0 per 10,000 depending on the nature of the population surveyed (Cullum 2016). A subsequent cross-sectional survey of people receiving community health services in one city in the UK estimated that 1.8 people per 10,000 have a pressure ulcer (Gray 2018).

Pressure ulcers confer a heavy burden in terms of personal impact and use of health-service resources. Having a pressure ulcer may impair physical, social, and psychological activities (Gorecki 2009). Ulceration impairs health-related quality of life (Essex 2009); can result in longer institution stays (Theisen 2012); and increases the risk of systemic infection (Espejo 2018). There is also substantial impact on health systems: a 2015 systematic review of 14 studies across a range of care settings in Europe and North America showed that costs related to pressure ulcer treatment ranged between EUR 1,71 and EUR 470.49 per person, per day (Demarré 2015). In the UK, the annual average cost to the National Health Service for managing one person with a pressure ulcer in the community was estimated to be GBP 1400 for a Stage 1 pressure ulcer and more than GBP 8500 for more severe stages (2015/2016 prices; Guest 2018). In Australia, the annual cost of treating pressure ulcers was estimated to be AUD 983 million (95% confidence interval (CI) 815 million to 1151 million) at 2012/2013 prices (Nguyen 2015). The serious consequences of pressure ulceration have led to an intensive focus on their prevention.

Description of the intervention

Pressure ulcers are considered largely preventable. Support surfaces are specialised medical devices designed to relieve or redistribute pressure on the body, or both, in order to prevent pressure ulcers (NPIAP S3I 2007). Types of support surface include, but are not limited to, integrated bed systems, mattresses and overlays (NPIAP S3I 2007). The NPIAP Support Surface Standards Initiative (S3I) system can be used to classify types of support surface (NPIAP S3I 2007). According to this system support surfaces may:

- be powered (i.e. require electrical power to function) or non-powered;
- passively redistribute body weight (i.e. reactive pressure redistribution), or mechanically alternate the pressure on the body to reduce the duration of pressure (i.e. active pressure redistribution);
- be made of a range of materials, including but not limited to: air cells, foam materials, fibre materials, gel materials, sheepskin for medical use and water-bags;
- be constructed of air-filled cells that have small holes on the surface for blowing out air to dry skin (i.e. low air-loss feature) or have fluid-like characteristics via forcing filtered air through ceramic beads (i.e. air-fluidised feature), or have neither of these features.

Full details of classifications of support surfaces are listed in Appendix 1. A widely used type of support surface is the reactive air bed or mattress (traditionally termed static air-filled bed or mattress). These beds or mattresses are made of air cells that remain constantly inflated with or without using electrically powered pumps (i.e. being static rather than dynamic) (Clark 2011; NPIAP S3I 2007). Reactive air beds or mattresses can have low-air-loss features designed to influence the microclimate environment by keeping the skin dry (since moisture is thought to potentially increase friction on skin and increase the risk of skin damage) (Clark 2011; Wounds International 2010). Some reactive air mattresses can have air-fluidised features.

Types of reactive air beds or mattresses include: powered or non-powered reactive air mattresses (e.g. Repose static air mattress); powered or non-powered reactive low-air-loss mattresses (e.g. Low Air Loss mattress); and powered or non-powered reactive air-fluidised air mattresses (e.g. Clinitron air-fluidised bed) (Shi 2018a).

How the intervention might work

The aim of using support surfaces to prevent pressure ulceration is to redistribute pressure beneath the body, thereby increasing blood flow to tissues and relieving the distortion of skin and soft tissue (Wounds International 2010). Reactive support surfaces achieve pressure redistribution by passive mechanisms, including immersion (i.e. ‘sinking’ of the body into a support surface) and envelopment (i.e. conforming of a support surface to the irregularities in the body). These devices distribute the pressure over a greater area, thereby reducing the magnitude of the pressure at specific sites (Clark 2011).

Why it is important to do this review

Support surfaces are widely used for preventing pressure ulcers, and are the focus of recommendations in international and
national guidelines (EPUAP/NPIAP/PPPIA 2019; NICE 2014). Since the publication of the Cochrane Review, 'Support surfaces for pressure ulcer prevention' (McInnes 2015), there has been a substantial increase in the number of relevant randomised controlled trials published in this area. The NPIAP S3I 2007 support surface-related terms and definitions have also been internationally recognised, and Cochrane has developed new methodological requirements, such as the use of GRADE assessments (Guyatt 2008). These developments necessitate an update of the evidence base.

In considering this evidence update, we took into account the size and complexity of the previously published review (McInnes 2015), which includes all types of support surface. An alternative approach is to split the original review into multiple new titles, each with a narrower focus. We consulted on this splitting option via an international survey in August 2019. The potential new titles suggested were based on clinical use, the new terms and definitions related to support surfaces (NPIAP S3I 2007), a relevant network meta-analysis (Shi 2018a), and current clinical practice guidelines (EPUAP/NPIAP/PPPIA 2019; NICE 2014). We received responses from 29 health professionals involved in pressure ulcer prevention activity in several countries (Australia, Belgium, China, Italy, the Netherlands and the UK). In total, 83% of respondents supported splitting the review into suggested titles and 17% were unsure (no respondent voted against splitting). The new review titles are as follows:

- alternating pressure (active) air surfaces for preventing pressure ulcers
- foam surfaces for preventing pressure ulcers
- reactive air surfaces for preventing pressure ulcers
- alternative reactive support surfaces (non-foam and non-air-filled) for preventing pressure ulcers

We will bring the results of these new reviews together in an overview with a network meta-analysis (Salanti 2012), in order to simultaneously compare all support surfaces and to rank them based on the probabilities of each being the most effective for preventing pressure ulcers. This particular review compares reactive air beds, mattresses or overlays with any surface.

**OBJECTIVES**

To assess the effects of reactive air beds, mattresses or overlays compared with any support surface on the incidence of pressure ulcers in any population in any setting.

**METHODS**

**Criteria for considering studies for this review**

**Types of studies**

We included published and unpublished randomised controlled trials (RCTs), including multi-armed studies, cluster-RCTs and crossover trials, regardless of the language of publication. We excluded studies using quasi-random allocation methods (e.g. alternation).

**Types of participants**

We included studies in any population, including those defined as being at risk of ulceration, as well as those with existing pressure ulcers at baseline (when the study measured pressure ulcer incidence).

**Types of interventions**

This review focused on reactive air beds or mattresses in general. Eligible studies included a specific bed, overlay or mattress with reactive or static pressure redistribution capabilities. These included, but were not limited to, specific reactive air mattresses identified in Shi 2018a; namely:

- powered or non-powered reactive air mattresses (e.g. Sofflex static air mattress); or
- powered or non-powered reactive low-air-loss mattresses (e.g. low-air-loss Hydrotherapy); or
- powered or non-powered reactive air-fluidised mattresses (e.g. Cliniton air-fluidised bed).

We included studies where two or more support surfaces were used sequentially over time or in combination, where the support surface(s) of interest were included in one of the study arms.

We included studies comparing eligible reactive air beds, overlays or mattresses against any comparator defined as a support surface. Comparators could be:

- non-reactive air surfaces, including: alternating pressure (active) air surfaces such as alternating pressure (or dynamic) air mattresses, foam mattresses, and non-foam and non-air-filled surfaces (e.g. reactive gel surfaces such as a gel pad used on an operating table, reactive fibre surfaces such as Silicore fibre overlay, reactive water surfaces, reactive sheepskin surfaces such as Australian Medical Sheepskins overlay), or
- a different type of reactive air surface.

We included studies in which co-interventions (e.g. repositioning) were delivered, provided that the co-interventions were the same in all arms of the study (i.e. interventions randomised were the only systematic difference).

**Types of outcome measures**

We considered the primary and secondary outcomes described below. If a study did not report any review-relevant outcomes but was otherwise eligible (i.e. eligible study design, participants and interventions), we contacted the study authors (where possible) to clarify whether they had measured a relevant outcome but did not report it. We considered the study as ‘awaiting classification’ if we could not establish whether it measured an outcome or not. We excluded the study if the study authors confirmed that they did not measure any review-relevant outcomes.

If a study measured an outcome at multiple time points, we considered the outcome measures at three months to be the primary endpoint for this review (Schoonhoven 2007), regardless of the time points specified as being of primary interest by the study. If the study did not report three-month outcome measures, we considered those closest to three months. Where a study only reported a single time point, we included this in this review. Where the study did not specify a time point for outcome measurement, we assumed this was the final duration of follow-up noted.
Primary outcomes

Our primary outcome was pressure ulcer incidence. We recorded two outcome measures (the proportion of participants developing a new pressure ulcer; and time to pressure ulcer incidence), where available. We considered the proportion of participants developing a new pressure ulcer as the primary outcome for this review. Our preferred measure was time to pressure ulcer incidence; however, we did not expect it to be reported in many studies. We extracted and analysed time-to-event data but focused on the binary outcome in our conclusions. We accepted the study authors’ definitions of an incident ulcer regardless of whether pressure ulcer severity classification system was used to measure or grade new pressure ulcers. We also considered the outcome of pressure ulcer incidence irrespective of whether studies reported ulcers by stages or as a non-stratified value.

We did not consider subjective outcome measures (e.g. ‘better’ or ‘worse’ skin condition) as measures of pressure ulcer incidence.

Secondary outcomes
- **Support-surface-associated patient comfort.** We considered patient comfort outcome data in this review only if the evaluation of patient comfort was pre-planned and was systematically conducted across all participants in the same way in a study. The definition and measurement of this outcome varied from one study to another; for example, the proportion of participants who report comfort, or comfort measured by a scale with continuous (categorical) numbers. We planned to include these data with different measurements in separate meta-analyses when possible.
- **All reported adverse events** (measured using surveys or questionnaires, other data capture process or visual analogue scale). We included data where study authors specified a clear method for collecting adverse event data. Where available, we extracted data on all serious and all non-serious adverse events as an outcome. We recorded where it was clear that events were reported at the participant level or whether multiple events per person were reported, in which case appropriate adjustments were required for data clustering (Peryer 2019). We considered the assessment of any event in general defined as adverse by participants, health professionals, or both.
- **Health-related quality of life** (measured using a standardised generic questionnaire such as EQ-5D (Herdmann 2011), 36-item Short Form (SF-36; Ware 1992), or pressure ulcer-specific questionnaires such as the PURPOSE Pressure Ulcer Quality of Life (PU-QOL) questionnaire (Gorecki 2013), at noted time points). We did not include ad hoc measures of quality of life or qualitative interviews of quality of life because these measures were unlikely to be validated.
- **Cost-effectiveness:** within-trial cost-effectiveness analysis comparing mean differences in effects with mean cost differences between the two arms. We extracted data on incremental mean cost per incremental gain in benefit (incremental cost-effectiveness ratio (ICER)). We also considered other measures of relative cost-effectiveness (e.g. net monetary benefit, net health benefit).

Search methods for identification of studies

**Electronic searches**

We searched the following electronic databases to identify reports of relevant clinical trials:

- the Cochrane Wounds Specialised Register (searched 14 November 2019);
- the Cochrane Central Register of Controlled Trials (CENTRAL; 2019, Issue 10) in the Cochrane Library (searched 14 November 2019);
- Ovid MEDLINE including In-Process & Other Non-Indexed Citations (1946 to 14 November 2019);
- Ovid Embase (1974 to 14 November 2019);
- EBSCO CINAHL Plus (Cumulative Index to Nursing and Allied Health Literature; 1937 to 14 November 2019).

The search strategies for the Cochrane Wounds Specialised Register, CENTRAL, Ovid MEDLINE, Ovid Embase and EBSCO CINAHL Plus can be found in Appendix 2. We combined the Ovid MEDLINE search with the Cochrane Highly Sensitive Search Strategy for identifying randomised trials in MEDLINE: sensitivity- and precision-maximising version (2008 revision) (Lefebvre 2019). We combined the Embase search with the Ovid Embase filter developed by the UK Cochrane Centre (Lefebvre 2019). We combined the CINAHL Plus search with the trial filter developed by (Glanville 2019). There were no restrictions with respect to language, date of publication or study setting.

We also searched the following clinical trials registries:

- US National Institutes of Health Ongoing Trials Register ClinicalTrials.gov (clinicaltrials.gov) (searched 20 November 2019);

Search strategies for clinical trials registries can be found in Appendix 2.

**Searching other resources**

For previous versions of McInnes 2015, the review authors of McInnes 2015 contacted experts in the field of wound care to enquire about potentially relevant studies that are ongoing or recently published. In addition, the review authors of McInnes 2015 contacted manufacturers of support surfaces for details of any studies manufacturers were conducting. This approach did not yield any additional studies; therefore, we did not repeat it for this review.

We identified other potentially eligible studies or ancillary publications by searching the reference lists of retrieved included studies, as well as relevant systematic reviews, meta-analyses and health technology assessment reports.

When necessary, we contacted authors of key papers and abstracts to request further information about their trials.

We did not perform a separate search for adverse effects of interventions used. We considered adverse effects described in included studies only.
Data collection and analysis
We carried out data collection and analysis according to the methods stated in the published protocol (Shi 2020), which were based on the Cochrane Handbook for Systematic Reviews of Interventions (Li 2019). Changes from the protocol or previously published versions of the review are documented in Differences between protocol and review.

Selection of studies
One review author re-checked the RCTs included in McInnes 2015 for eligibility (CS). Two review authors or researchers (CS and Asmara Jammali-Blasi, or JCD) independently assessed the titles and abstracts of the new search results for relevance using Rayyan (Ouzzani 2016) (Differences between protocol and review), and then independently inspected the full text of all potentially eligible studies. The two review authors or researchers (CS and Asmara Jammali-Blasi, or JCD) resolved any disagreements through discussion or by involving another review author if necessary.

Data extraction and management
One review author checked data from the studies included in McInnes 2015 and extracted additional data where necessary (CS). A second review author or researcher checked any new data extracted (SR, VL, EM, Zhenmi Liu, Gill Norman, or Melanie Stephens). For new included studies, one review author (CS) independently extracted data and another review author or researcher checked all data (SR, VL, EM, Zhenmi Liu, Gill Norman, or Melanie Stephens) (Differences between protocol and review). Any disagreements were resolved through discussion and, if necessary, with the involvement another review author. Where necessary, we contacted the authors of included studies to clarify data.

We extracted these data using a pre-prepared data extraction form:

- basic characteristics of studies (first author, publication type, publication year and country);
- funding sources;
- care setting;
- characteristics of participants (trial eligibility criteria, average age in each arm or in a study, proportions of participants by gender and participants’ baseline skin status);
- support surfaces being compared (including their descriptions);
- details on any co-interventions;
- duration of follow-up;
- the number of participants enrolled;
- the number of participants randomised to each arm;
- the number of participants analysed;
- participant withdrawals with reasons;
- the number of participants developing new ulcers (by ulcer stages where possible);
- data on time to pressure ulceration;
- support-surface-associated patient comfort;
- adverse event outcome data;
- health-related quality of life outcome data; and
- cost-effectiveness outcome data.

We (CS and NC) classified specific support surfaces in the included studies into intervention groups using the NPIAP S3I support surface-related terms and definitions (NPIAP S3I 2007). Therefore, to accurately assign specific support surfaces to intervention groups, we extracted full descriptions of support surfaces from included studies, and when necessary supplemented the information with that from external sources such as other publications about the same support surface, manufacturers’ or product websites and expert clinical opinion (Shi 2018b). If we were unable to define any of the specific support surfaces evaluated in an included study, we extracted available data and reported these as additional data outside the main review results.

Assessment of risk of bias in included studies
Two review authors or researchers (CS and SR, VL, EM, Zhenmi Liu, Gill Norman, or Melanie Stephens) independently assessed risk of bias of each included study using the Cochrane ‘Risk of bias’ tool (see Appendix 3). This tool has seven specific domains: sequence generation (selection bias), allocation concealment (selection bias), blinding of participants and personnel (performance bias), blinding of outcome assessment (detection bias), incomplete data (attrition bias), selective outcome reporting (reporting bias), and other issues (Higgins 2017). We assessed performance bias, detection bias and attrition bias separately for each of the review outcomes (Higgins 2017). We noted that it is often impossible to blind participants and personnel in device trials. In this case, performance bias may be introduced if knowledge of treatment allocation results in deviations from intended interventions, differential use of co-interventions or care between groups not specified in the study protocol that may influence outcomes. We attempted to understand if, and how, included studies compensated for challenges in blinding; for example, implementing strict protocols to maximise consistency of co-interventions between groups to reduce the risk of performance bias. We also noted that pressure ulcer incidence is a subjective outcome. Compared with blinded assessment, non-blinded assessment of subjective outcomes tends to be associated with more optimistic effect estimates of experimental interventions in RCTs (Hróbjartsson 2012). Therefore, we judged non-blinded outcome assessment as being at high risk of detection bias. In this review, we included the issues of differential diagnostic activity and unit of analysis under the domain of 'other issues'. For example, unit of analysis issues occurred where a cluster-randomised trial had been undertaken but analysed at the individual level in the study report.

For the studies included in McInnes 2015, one review author (CS) checked the ‘Risk of bias’ judgements and, where necessary, updated them. A second review author or researcher (SR, VL, EM, Zhenmi Liu, Gill Norman, or Melanie Stephens) checked any updated judgement. We assigned each ‘Risk of bias’ domain a judgement of high, low, or unclear risk of bias. We resolved any discrepancy through discussion and by involving another review author where necessary. Where possible, useful and feasible, when a lack of reported information resulted in a judgement of unclear risk of bias, we planned to contact study authors for clarification.

We present our assessment of risk of bias for the proportion of participants developing a new pressure ulcer outcome using two ‘Risk of bias’ summary figures. One is a summary of bias for each item across all studies, and the second shows a cross-tabulation of each study by all of the ‘Risk of bias’ items.
Once we had given our judgements for all ‘Risk of bias’ domains, we judged the overall risk of bias for each outcome across studies as:

- low risk of bias, if we judged all domains to be at low risk of bias;
- unclear risk of bias, if we judged one or more domains to be at unclear risk of bias and other domains were at low risk of bias but no domain was at high risk of bias; or
- high risk of bias, as long as we judged one or more domains as being at high risk of bias, or all domains had unclear ‘Risk of bias’ judgements, as this could substantially reduce confidence in the result.

We resolved any discrepancy between review authors through discussion and by involving another review author where necessary. For studies using cluster randomisation, we planned to consider the risk of bias in relation to recruitment bias, baseline imbalance, loss of clusters, incorrect analysis and comparability with individually randomised studies (Eldridge 2019; Higgins 2019; Appendix 3). However, we did not include any studies with a cluster design.

Measures of treatment effect

For meta-analysis of pressure ulcer incidence data, we present the risk ratio (RR) with its 95% confidence interval (CI). For continuous outcome data, we present the mean difference (MD) with 95% CIs for studies that use the same assessment scale. If studies reporting continuous data used different assessment scales, we planned to report the standardised mean difference (SMD) with 95% CIs. However, this was not undertaken in the review.

For time-to-event data (time to pressure ulcer incidence), we present the hazard ratio (HR) with its 95% CI. If included studies reporting time-to-event data did not report an HR, when feasible, we estimated this using other reported outcomes (such as numbers of events) through employing available statistical methods (Parmar 1998; Tierney 2007).

Unit of analysis issues

We noted whether studies presented outcomes at the level of cluster (e.g. ward, research site) or at the level of participants. We also recorded whether the same participant was reported as having multiple pressure ulcers.

Unit of analysis issues may occur if studies randomise at the cluster level but the incidence of pressure ulcers is observed and data are presented and analysed at the level of participants (clustered data). We noted whether data regarding participants within a cluster were (incorrectly) treated as independent within a study, or were analysed using within-cluster analysis methods. If clustered data were incorrectly analysed, we recorded this as part of the ‘Risk of bias’ assessment.

If a cluster-RCT was not correctly analysed, we planned to use the following information to adjust for clustering ourselves where possible, in accordance with guidance in the Cochrane Handbook for Systematic Reviews of Interventions (Higgins 2019).

- The number of clusters randomly assigned to each intervention, or the average (mean) number of participants per cluster.
- Outcome data ignoring the cluster design for the total number of participants.
- Estimate of the intra-cluster (or intra-class) correlation coefficient (ICC).

However, we did not identify any cluster-RCTs in this review.

Cross-over trials

For cross-over trials, we only considered outcome data at the first intervention phase (i.e. prior to cross-over) as eligible.

Studies with multiple treatment groups

If a study had more than two eligible study groups, where appropriate, we combined results across these arms to make single pair-wise comparisons (Higgins 2019).

Dealing with missing data

Data are commonly missing from study reports. Reasons for missing data could be the exclusion of participants after randomisation, withdrawal of participants from a study, or loss to follow-up. The exclusion of these data from analysis may break the randomisation and potentially introduces bias.

Where there were missing data, and where relevant, we contacted study authors to pose specific queries about these data. In the absence of other information, for pressure ulcer incidence we assumed that participants with missing data did not develop new pressure ulcers for the main analysis (i.e. we added missing data to the denominator but not the numerator). We examined the impact of this assumption through undertaking a sensitivity analysis (see Sensitivity analysis). When a study did not specify the number of randomised participants prior to dropout, we used the available number of participants as the number randomised.

Assessment of heterogeneity

Assessing heterogeneity can be a complex, multifaceted process. Firstly, we considered clinical and methodological heterogeneity; that is, the extent to which the included studies varied in terms of participant, intervention, outcome, and other characteristics including duration of follow-up, clinical settings, and overall study-level ‘Risk of bias’ judgement (Deeks 2019). In terms of the duration of follow-up, in order to assess the relevant heterogeneity, we recorded and categorised assessment of outcome measures as follows:

- up to eight weeks (short-term);
- more than eight weeks to 16 weeks (medium-term); and
- more than 16 weeks (long-term).

We supplemented this assessment of clinical and methodological heterogeneity with information regarding statistical heterogeneity assessed using the Chi² test. We considered a P value of less than 0.10 to indicate statistically significant heterogeneity given that the Chi² test has low power, particularly in the case where studies included in a meta-analysis have small sample sizes. We carried out this statistical assessment in conjunction with the I² statistic (Higgins 2003), and the use of prediction intervals for random-effects meta-analyses (Borenstein 2017; Riley 2011).

The I² statistic is the percentage of total variation across studies due to heterogeneity rather than chance (Higgins 2003). Very broadly, we considered that I² values of 25% or less may indicate a low level of heterogeneity and values of 75% or more may indicate very high
heterogeneity (Higgins 2003). For random-effects models where the meta-analysis had more than 10 included studies and no clear funnel plot asymmetry, we also planned to present 95% prediction intervals (Deeks 2019). We planned to calculate prediction intervals following methods proposed by Borenstein 2017.

Random-effects analyses produce an average treatment effect, with 95% confidence intervals indicating where the true population average value is likely to lie. Prediction intervals quantify variation away from this average due to between-study heterogeneity. The interval conveys where a future study treatment effect estimate is likely to fall based on the data analysed to date (Riley 2011). Prediction intervals are always wider than confidence intervals (Riley 2011).

It is important to note that prediction intervals reflect heterogeneity of any source, including from methodological issues as well as clinical variation. For this reason some authors have suggested that prediction intervals are best calculated for studies at low risk of bias to ensure intervals that have meaningful clinical interpretation (Riley 2011). We had planned to calculate prediction intervals for all analyses to assess heterogeneity and then to explore the impact of risk of bias in subgroup analysis stratified by study risk of bias assessment as detailed below. However, we did not calculate any prediction interval because all conducted meta-analyses contained fewer than 10 studies.

**Assessment of reporting biases**

We followed the systematic framework recommended by Page 2019 to assess risk of bias due to missing results (non-reporting bias) in the meta-analysis of pressure ulcer incidence data. To make an overall judgement about risk of bias due to missing results, we did the following.

- Identified whether pressure ulcer incidence data were unavailable by comparing the details of outcomes in trials registers, protocols or statistical analysis plans (if available) with reported results. If the above information sources were unavailable, we compared outcomes in the conference abstracts or in the methods section of the publication, or both, with the reported results. If we found non-reporting of study results, we then judged whether the non-reporting was associated with the nature of findings by using the ‘Outcome Reporting Bias In Trials’ (ORBIT) system (Kirkham 2018).
- Assessed the influence of definitely missing pressure ulcer incidence data on meta-analysis.
- Assessed the likelihood of bias where a study had been conducted but not reported in any form. For this assessment, we considered whether the literature search was comprehensive and planned to produce a funnel plot for meta-analysis for seeking more evidence about the extent of missing results, provided there were at least 10 included studies (Peters 2008; Salanti 2014).

However, we did not produce a funnel plot for any meta-analysis because all analyses in this review had fewer than 10 included studies.

**Data synthesis**

We summarised the included studies narratively and synthesised included data by using meta-analysis where applicable. We structured comparisons according to type of comparator and then by outcomes, ordered by follow-up period.

We considered clinical and methodological heterogeneity and undertook pooling when studies appeared appropriately similar in terms of participants, support surfaces, and outcome type. Where statistical synthesis of data from more than one study was not possible or considered inappropriate, we conducted a narrative review of eligible studies.

Once the decision to pool was made, we used a random-effects model, which estimated an underlying average treatment effect from studies. Conducting meta-analysis with a fixed-effect model in the presence of even minor heterogeneity may provide overly narrow confidence intervals. We used the Chi² test and I² statistic to quantify heterogeneity but not to guide choice of model for meta-analysis (Borenstein 2009). We exercised caution when meta-analysed data were at risk of small-study effects because use of a random-effects model may be unsuitable in this situation. In this case, or where there were other reasons to question the choice of a fixed-effect or random-effects model, we assessed the impact of the approach using sensitivity analyses to compare results from alternate models (Thompson 1999).

We performed meta-analyses largely using Review Manager 5.4 (Review Manager 2020). We presented data using forest plots where possible. For dichotomous outcomes, we presented the summary estimate as a RR with 95% CIs. Where continuous outcomes were measured, we presented the MD with 95% CIs; we planned to report SMD estimates where studies measured the same outcome using different methods. For time-to-event data, we presented the summary estimates as HRs with 95% CIs.

**Subgroup analysis and investigation of heterogeneity**

**Investigation of heterogeneity**

When important heterogeneity occurred, we planned to follow these steps, proposed by Cipriani 2013 and Deeks 2019, to investigate further:

- check the data extraction and data entry for errors and possible outlying studies;
- if outliers existed, perform sensitivity analysis by removing them; and
- if heterogeneity was still present, we planned to perform subgroup analyses for study-level characteristics (see below) in order to explain heterogeneity as far as possible. However, we did not undertake any subgroup analysis because meta-analyses in this review included fewer than 10 studies.

**Subgroup analysis**

We investigated heterogeneity using the methods described in the Cochrane Handbook for Systematic Reviews of Interventions (Deeks 2019). We planned to perform subgroup analyses for binary and categorical factors (or meta-regression for continuous factors) to determine whether the size of treatment effects was influenced by these four study-level characteristics:

- risk of bias (binary: low or unclear risk of bias; and high risk of bias (Schulz 1995));
• settings (categorical: acute care and other hospital settings; long-term care settings; operating theatre setting; and intensive care unit);
• baseline skin status (categorical: participants at risk, of mixed skin status or non-reporting; non-blanchable erythema; existing ulcers of Stage 2 or serious (Shi 2018c)); and
• follow-up duration (continuous).

We did not perform subgroup analysis or meta-regression when the number of studies included in the meta-analysis was not reasonable (i.e. fewer than 10).

We planned to compare subgroup findings using the 'Test for Subgroup Differences' in Review Manager 5.4 (Review Manager 2020).

Sensitivity analysis
We conducted sensitivity analyses for the following factors, to assess the robustness of meta-analysis of data on pressure ulcer incidence.

- Impact of the selection of pressure ulcer incidence outcome measure. The proportion of participants developing a new pressure ulcer was the primary outcome measure for this review but we also analysed time to pressure ulcer development, where data were available.
- Impact of missing data. The primary analysis assumed that participants with missing data did not develop new pressure ulcers. We also analysed pressure ulcer incidence by only including data for the participants for whom we had endpoint data (complete cases). We noted that when a study only had complete case data (i.e. missing data or the numbers of participants randomised were not reported), complete case data were considered in the related main analysis (Differences between protocol and review).
- Impact of altering the effects model used. We used a random-effects model for the main analysis followed by a fixed-effect analysis.

Summary of findings and assessment of the certainty of the evidence
We presented the main, pooled results of the review in 'Summary of findings' tables, which we created using GRADEpro GDT software. These tables present key information concerning the certainty of evidence, the magnitude of the effects of the interventions examined and the sum of available data for the main outcomes (Schünemann 2019). The tables also include an overall grading of the certainty of the evidence associated with each of the main outcomes that we assessed using the GRADE approach. The GRADE approach defines the certainty of a body of evidence as the extent to which one can be confident that an estimate of effect or association is close to the true quantity of specific interest.

The GRADE assessment involves consideration of five factors: within-trial risk of bias, directness of evidence, heterogeneity, precision of effect estimates, and risk of publication bias (Schünemann 2019). The certainty of evidence can be assessed as being high, moderate, low or very low; RCT evidence has the potential to be high-certainty. We did not downgrade the certainty of evidence for the risk of bias factor in a specific circumstance. That is, if the blinding of participants and personnel was the only domain resulting in our judgement of overall high risk of bias for the included studies; however for these studies it was impossible to blind participants and personnel.

When downgrading for imprecision, we followed the methods described in Guyatt 2011: either considering both the optimal information size (OIS) and the 95% CI of each meta-analysis if they were estimable; or considering the sample size, the number of events and other effectiveness indicators if the calculation of OIS and undertaking a meta-analysis were not applicable. Where necessary, we used the GRADE 'default' minimum important difference values (RR = 1.25 and 0.75) as the thresholds to judge if a 95% CI was wide (imprecise) so as to include the possibility of clinically important harm and benefit (Guyatt 2011).

We presented a separate 'Summary of findings' table for all but one comparison evaluated in this review. The exception was the comparison of reactive air surfaces versus another type of reactive air surface (Differences between protocol and review). We presented these outcomes in the 'Summary of findings' tables:
- proportion of participants developing a new pressure ulcer;
- time to pressure ulcer incidence;
- support-surface-associated patient comfort;
- all reported adverse events;
- health-related quality of life; and
- cost-effectiveness.

We prioritised the time points and method of outcome measurement specified in Types of outcome measures for presentation in 'Summary of findings' tables. Where we did not pool data for some outcomes within a comparison, we conducted a GRADE assessment for each of these outcomes and presented these assessments in a narrative format in 'Summary of findings' tables (Differences between protocol and review).

RESULTS
Description of studies
See Characteristics of included studies; Characteristics of excluded studies; Characteristics of studies awaiting classification; Characteristics of ongoing studies.

Results of the search
The electronic searches identified 1624 records, including 1164 from electronic databases and 460 from trial registries. We excluded 218 duplicate records and screened 1406 records, of which 233 were identified as potentially eligible and obtained as full-text. Following full-text screening, we considered 18 records of 16 studies eligible for inclusion in this review (Beeckman 2019; Bennett 1998; Cavicchioli 2007; Cobb 1997; Cooper 1998; Finnegan 2008; Inman 1993; Jiang 2014; Lazzara 1991; Malbrain 2010; Price 1999; Sideranok 1992; Takala 1996; Van Leen 2011; Van Leen 2013; Vermette 2012).

From other resources, one further eligible study, Allman 1987, was identified by scanning the reference lists of the 14 systematic reviews or meta-analyses that were identified from electronic searches (Chou 2013; Huang 2013; McGinnis 2011; McInnes 2015; McInnes 2018; Mistiaen 2010a; De Oliveira 2017; Rae 2018; Reddy 2006; Reddy 2008; Serraes 2018; Shi 2018a; Smith 2013; Yao 2018),
as well as the clinical practice guidelines listed in Searching other resources. In total, we included 17 studies (with 19 publications) in the review, of which one was an unpublished report (Cobb 1997). See Figure 1.
Figure 1. Study flow diagram

1624 records identified through electronic searches (including 1164 from electronic databases and 460 from trial registries) → 6 additional records identified through other sources (including scanning the reference lists of 14 relevant systematic reviews identified in database searches; tracking relevant trial registry records)

1412 records after duplicates removed → 1412 records screened

1178 records excluded

(1) 154 studies with 201 full-text articles excluded, with reasons:
- Irrelevant and ineligible interventions (e.g., other beds or mattresses, heel suspending devices, cushions; 67 studies)
- Ineligible study design (e.g., non-RCT, reviews, commentary articles; 52 studies)
- Studies focused on the treatment rather than prevention of pressure ulcers (20 studies)
- Incorrect randomisation and non-randomised methods (eight studies)
- Studies with ineligible outcomes (e.g., the breakdown of flaps after operations, interface pressure; four studies)
- Clinical trials that were withdrawn (two studies)
- Ineligible participants (healthy
Included studies

Types of studies

Of the 17 included RCTs, 16 had a parallel group design; 15 with two arms, and one with three arms (Sideranko 1992). One study was a two-arm, cross-over design trial and we only considered data prior to cross-over in this review (Van Leen 2013).

Of the 17 studies, four were conducted at more than one research site (Beeckman 2019; Bennett 1998; Cavicchioli 2007; Jiang 2014). Except for one study conducted in China (Jiang 2014), all of the included studies were conducted in high-income and upper-middle-income economies in Europe and North America, including Belgium (Beeckman 2019; Malbrain 2010), Canada (Inman 1993; Vermette 2012), Finland (Takala 1996), Italy (Cavicchioli 2007), the Netherlands (Van Leen 2011; Van Leen 2013), the UK (Cooper 1998; Price 1999) and the USA (Allman 1987; Bennett 1998; Cobb 1997; Finnegan 2008; Lazzara 1991; Sideranko 1992). Of the included studies, the median of the duration of follow-up was 14 days (range: five days to six months).

Types of participants

Age and sex at baseline

The 17 included studies enrolled a total of 2604 participants (median study sample size: 83 participants; range: 16 to 1074). The average participant age was specified for 16 studies and ranged between 56 and 87 years (median: 72 years). Bennett 1998 did not specify the average participant age but stated that all participants were more than 80 years old. The sex of the participants was specified for 2511 participants in the 17 studies: 1125 (44.8%) were male and 1386 (55.2%) were female.

Skin status at baseline

Of the 17 studies, 13 (2335 participants) recruited people at risk of having a new ulcer with risk assessed largely using the Waterlow, Norton or Braden scales. In 10 of the 13 studies, 2033 (87.1%) participants were free of pressure ulcers at baseline. In three studies, 302 (12.9%) participants with superficial ulcers were enrolled (Bennett 1998; Cavicchioli 2007; Malbrain 2010). In two studies, 112 participants with existing severe full-thickness pressure ulcers were enrolled (Allman 1987; Finnegan 2008). One study (100 participants; Inman 1993) did not specify the skin status at baseline, and the final included study (57 participants; Sideranko 1992) stated that all participants were free of ulcers at baseline.

Care settings

Participants were recruited from a variety of settings, including:

- a mixture of acute care and long-term care settings (two studies: Bennett 1998; Cavicchioli 2007);
- acute care settings (including accident and emergency departments, and hospitals in general) (seven studies: Allman 1987; Cobb 1997; Cooper 1998; Finnegan 2008; Jiang 2014; Price 1999; Vermette 2012);
- intensive care units (four studies: Inman 1993; Malbrain 2010; Sideranko 1992; Takala 1996); and
- community and long-term care settings (including nursing homes and geriatric units) (four studies: Beeckman 2019; Lazzara 1991; Van Leen 2011; Van Leen 2013).

Types of interventions

A wide range of reactive air surfaces was investigated, including:

- air-fluidised beds (Allman 1987; Finnegan 2008); Repose static air mattress (Beeckman 2019; Price 1999); Soflex mattress (Cooper 1998); the continuous low pressure modality of Hill-Rom Duo2 (Cavicchioli 2007); EHOB WAFFLE static air mattress (Jiang 2014; Cobb 1997; Vermette 2012); ROHO dry flotation mattress overlay (Malbrain 2010; Cooper 1998); Gaymar SofCare air-filled overlay (Lazzara 1991; Sideranko 1992); low-air-loss hydrotherapy (Bennett 1998); KinAir air suspension bed (Inman 1993; Cobb 1997); Carital Optima constant low pressure air mattress (Takala 1996); and static air overlay applied on top of foam mattresses (Van Leen 2011; Van Leen 2013).

These reactive air surfaces, low-air-loss hydrotherapy (Bennett 1998) and KinAir air suspension bed (Inman 1993; Cobb 1997) have a low-air-loss feature.

Full details of reactive air surfaces and comparators are listed in Effects of interventions below. Three studies (326 participants) used comparator group surfaces that we could not classify using the NPIAP S31 support surface terms and definitions: two (216 participants) termed their control surfaces as ‘standard hospital surfaces’ (Bennett 1998; Inman 1993) and one (110 participants) used alternating pressure (active) air surfaces for 5 of 55 control
participants and RIK® microfluid static overlay for the remaining 50 of 55 control participants (Vermette 2012).

Eleven studies specified the co-interventions they applied (e.g. repositioning, cushions) (Beeckman 2019; Bennett 1998; Cooper 1998; Finnegan 2008; Inman 1993; Jiang 2014; Malbrain 2010; Price 1999; Van Leen 2011; Van Leen 2013; Vermette 2012). All but one of these stated or indicated that the same co-interventions were applied in all study groups. However, Inman 1993 stated that two-hourly repositioning was applied in the standard hospital surface arm but did not specify if any co-intervention was applied in the reactive air surfaces arm.

Funding sources
Of the 17 studies, 12 specified the details of funding sources, including nine that were completely or partly funded by industry or received mattresses under evaluation from industries (Allman 1987; Beeckman 2019; Bennett 1998; Cooper 1998; Finnegan 2008; Inman 1993; Lazzara 1991; Price 1999; Takala 1996). Jiang 2014 was supported by public funding, and two studies noted no funding support (Van Leen 2011; Vermette 2012).

Excluded studies
We excluded 154 studies (with 201 records). The main reasons for exclusion were: irrelevant or ineligible interventions (67 studies); ineligible study design (e.g. non-RCT, reviews, commentary articles; 52 studies); studies focused on the treatment rather than prevention of pressure ulcers (20 studies); incorrect randomisation and non-randomised methods (eight studies); studies with ineligible outcomes (four studies); clinical trials that were withdrawn (two studies; NCT02634892; NCT02735135); and ineligible participants (healthy subjects; one study). We also identified eight duplicates in screening the full-texts (see Figure 1).

Ongoing studies
We did not identify any ongoing studies.

Studies awaiting classification
There were six studies (six records) for which we could not make eligibility decisions. In one case (Gardner 2008), we were unable to determine whether the study used foam surfaces. For the five remaining studies, we were unable to obtain the full-texts (in part due to more limited access to intra-library loans during the COVID–19 period) despite making extensive efforts (Chaloner 2000b; Henn 2004; Knight 1999; Mastrangelo 2010a; Melland 1998).

Risk of bias in included studies
We summarise ‘Risk of bias’ assessments for the primary outcome of this review in Figure 2 and Figure 3.
Figure 2. Risk of bias summary: review authors' judgements about each risk of bias item for each included study

</tbody>
</table>
We judged 10 of the 17 studies to have an unclear overall risk of bias for the primary outcome (Allman 1987; Cobb 1997; Cooper 1998; Inman 1993; Jiang 2014; Lazzara 1991; Malbrain 2010; Sideranko 1992; Van Leen 2011; Van Leen 2013). We judged all remaining seven studies as having findings at high overall risk of bias, all having one or more domains with high risk of bias judgement (Beeckman 2019; Bennett 1998; Cavicchioli 2007; Finnegan 2008; Price 1999; Takala 1996; Vermette 2012). Of these seven studies, five had high risk of bias judgement for the primary outcome in the domains of blinding of participants and personnel, blinding of outcome assessment, or both (Beeckman 2019; Finnegan 2008; Price 1999; Takala 1996; Vermette 2012).

Publication bias

We ran a comprehensive search and considered the risk of having missed published reports to be low. We were able to locate one study from other resources and one unpublished report (Allman 1987 and Cobb 1997, respectively). We were unable to assess the risk of non-publication of studies with negative findings as we could not present funnel plots given the small number of included studies in each analysis.

Effects of interventions

See: Summary of findings 1 Reactive air surfaces compared with alternating pressure (active) air surfaces for pressure ulcer prevention; Summary of findings 2 Reactive air surfaces compared with foam surfaces for pressure ulcer prevention; Summary of findings 3 Reactive air surfaces compared with reactive water surfaces for pressure ulcer prevention; Summary of findings 4 Reactive air surfaces compared with reactive gel surfaces for pressure ulcer prevention

See Summary of findings 1; Summary of findings 2; Summary of findings 3; Summary of findings 4.

Unless otherwise stated, random-effects analysis was used throughout. Each pooled result presented is an average effect, rather than a common effect and should be interpreted as such.

We have not reported data from the three studies with comparator group surfaces that we could not classify in the main body of the results (Bennett 1998; Inman 1993; Vermette 2012). For completeness, we summarise the results of these studies in Appendix 4.

Figure 3. Risk of bias graph: review authors’ judgements about each risk of bias item presented as percentages across all included studies

Low risk of bias Unclear risk of bias High risk of bias

We performed data analyses for the following comparisons and outcomes. Where applicable, we performed pre-specified sensitivity analyses as noted in Sensitivity analysis.

Comparison 1: Reactive air surfaces versus alternating pressure (active) air surfaces (seven studies, 1728 participants)

Seven studies compared reactive air surfaces with alternating pressure (active) air surfaces (Beeckman 2019; Cavicchioli 2007; Finnegan 2008; Jiang 2014; Malbrain 2010; Price 1999; Sideranko 1992).

Primary outcomes

Proportion of participants developing a new pressure ulcer (follow-up duration median 14 days, minimum 5 days, maximum 15 days)

Six studies (1648 participants) reported this outcome (Beeckman 2019; Cavicchioli 2007; Finnegan 2008; Jiang 2014; Malbrain 2010; Sideranko 1992) and their data were pooled. It is uncertain if there is a difference in the proportion of participants developing a new ulcer between reactive air surfaces (19/849 (2.2%)) and alternating pressure (active) air surfaces (32/799 (4.0%)). The RR is 0.62 (95% CI 0.35 to 1.11; I² = 3%; Analysis 1.1). Evidence is of very low certainty, downgraded twice for high risk of bias in domains other than performance bias for four studies contributing over 54% weight in the meta-analysis, and once for imprecision as, despite the fact that the OIS was met, the 95% CI was wide and crossed RR = 0.75.

Subgroup analysis

We considered the studies in Analysis 1.1 as heterogeneous in terms of care settings, skin status at baseline and overall ‘Risk of bias. However, we did not perform any pre-specified subgroup analysis because, as noted in Subgroup analysis and investigation of heterogeneity, the number of included studies was fewer than 10, meaning it would be difficult to meaningfully interpret the results.

Sensitivity analyses

- Sensitivity analysis with complete case data. This resulted in a RR of 0.62 (95% CI 0.35 to 1.11; I² = 3%). The result was consistent with the main analysis (Appendix 5).
- Sensitivity analysis with fixed-effect (rather than random-effects) model. The use of a fixed-effect model resulted in a RR
of 0.58 (95% CI 0.34 to 1.00; I² = 3%) and this was consistent with the main analysis (Appendix 5).

- **Sensitivity analysis with time to pressure ulcer incidence as the primary outcome (follow-up duration 14 days)**. Only Beeckman 2019 (308 participants) reported this outcome. Low-certainty evidence suggests that people treated with reactive air surfaces may be at lower risk of developing a new pressure ulcer than those treated with alternating pressure (active) air surfaces over 14 days’ follow-up in a nursing home setting (HR 0.44, 95% CI 0.21 to 0.96; Analysis 1.2). These results are sensitive to the choice of format for the primary outcome measure so they should be interpreted cautiously. Evidence certainty was downgraded twice for high risk of detection bias (Appendix 5).

**Secondary outcomes**

**Support-surface-associated patient comfort (median follow-up duration 11 days, minimum 5 days, maximum 14 days)**

Four studies (1364 participants) reported this outcome (Cavicchioli 2007; Finnegan 2008; Jiang 2014; Price 1999). The four studies reported a range of different measures for this outcome and they cannot be pooled (see Table 2). We are uncertain if there is a difference in patient comfort between reactive air surfaces and alternating pressure (active) air surfaces. Evidence was of very low certainty, downgraded once for high overall risk of bias in three small studies but unclear risk of bias in one large study, and twice for substantial inconsistency.

**All reported adverse events**

Not reported.

**Health-related quality of life**

Not reported.

**Cost-effectiveness**

Not reported.

**Comparison 2: Reactive air surfaces versus foam surfaces (four studies, 236 participants)**

Four studies (236 participants) compared reactive air surfaces with foam surfaces (Allman 1987; Takala 1996; Van Leen 2011; Van Leen 2013). Of these studies, Allman 1987 compared reactive air surfaces with the use of foam surfaces (19 mm thick foam pad) on top of alternating pressure (active) air surfaces.

**Primary outcomes**

**Proportion of participants developing a new pressure ulcer (follow-up duration minimum 13 days, maximum 6 months)**

All four studies (236 participants) reported this outcome and the data of 229 participants were available for analysis. Reactive air surfaces (12/113 (10.6%)) may reduce the proportion of participants developing a new pressure ulcer compared with foam surfaces (32/116 (27.6%)); however, the evidence is of low certainty. The RR is 0.42 (95% CI 0.18 to 0.96; I² = 25%; Analysis 2.1). Evidence certainty was downgraded once for risk of bias (one study contributing 8% weight in the meta-analysis had domains other than performance bias at high risk of bias and all the remaining studies had domains other than performance bias at unclear risk of bias) and once for imprecision as, despite the fact that the OIs was met, the 95% CI crossed RR = 0.75.

The included studies did not report data on time to pressure ulcer incidence.

**Subgroup analysis**

We considered the studies in Analysis 2.1 as heterogeneous in terms of follow-up durations, care settings, and overall ‘risk of bias’ and there was an indication of statistical heterogeneity (Tau² = 0.21, Chi² test P value = 0.26 and I² = 25%). We did not perform any pre-specified subgroup analysis because, as noted in Subgroup analysis and investigation of heterogeneity, the number of included studies was fewer than 10, meaning it would be difficult to meaningfully interpret the results.

**Sensitivity analyses**

- **Sensitivity analysis with fixed-effect (rather than random-effects) model**. The use of a fixed-effect model resulted in a RR of 0.40 (95% CI 0.23 to 0.72; I² = 25%). This remained consistent with the main analysis (Appendix 5).

**Secondary outcomes**

**Support-surface-associated patient comfort (follow-up duration 13 days)**

Only Allman 1987 (72 participants) reported this outcome in which participants were asked to choose a response to a comfort-related question from these categories: ‘Very comfortable’, ‘Comfortable’, ‘Uncomfortable’, or ‘Very uncomfortable’. It is uncertain if there is a difference in patient comfort responses between reactive air surfaces and foam surfaces on top of an alternating pressure (active) air surface (P = 0.04; very low-certainty evidence). Evidence certainty was downgraded once for unclear risk of bias, and twice for imprecision due to the small sample size.

**All reported adverse events (follow-up duration 13 days)**

Only Allman 1987 (72 participants) reported this outcome (see Table 1). It is uncertain if there is a difference in adverse event rates between reactive air surfaces and foam surfaces (very low-certainty evidence). Evidence certainty was downgraded once for unclear risk of bias, and twice for imprecision due to the small sample size.

**Health-related quality of life**

Not reported.

**Cost-effectiveness**

Not reported.

**Comparison 3: Reactive air surfaces versus reactive water surfaces (one study, 37 participants)**

Sideranko 1992 compared reactive air surfaces with a reactive water mattress.

**Primary outcomes**

**Proportion of participants developing a new pressure ulcer (follow-up duration 9.5 days)**

Sideranko 1992 (37 participants) reported this outcome. It is uncertain if there is a difference in the proportion of participants developing a new ulcer between reactive air surfaces (1/20 (5%)) and reactive water surfaces (2/17 (11.8%)). The RR is 0.43 (95% CI 0.04 to 4.29; Analysis 3.1). Evidence is of very low certainty, downgraded once for unclear overall risk of bias and twice for...
substantial imprecision because the OIS was not met and the 95% CI was very wide and crossed both RRs = 0.75 and 1.25.

The included study did not report data on time to pressure ulcer incidence.

**Secondary outcomes**

Not reported.

**Comparison 4: Reactive air surfaces versus reactive gel surfaces (one study, 74 participants)**

Lazzara 1991 compared reactive air surfaces with a reactive gel mattress.

**Primary outcomes**

Proportion of participants developing a new pressure ulcer (follow-up duration of 6 months)

Lazzara 1991 (74 participants) reported this outcome and had analysable data for 66 participants. It is uncertain if there is a difference in the proportion of participants developing a new ulcer between reactive air surfaces (10/33 (30.3%)) and reactive gel surfaces (8/33 (24.2%)). The RR is 1.25 (95% CI 0.56 to 2.77; Analysis 4.1). Evidence is of very low certainty, downgraded once for unclear risk of bias and twice for imprecision because the OIS was not met and the confidence interval was very wide, and crossed both RRs = 0.75 and 1.25.

The included study did not report data on time to pressure ulcer incidence.

**Secondary outcomes**

Not reported.

**Comparison 5: Comparison between two types of reactive air surfaces (two studies, 223 participants)**

Two studies compared two different types of reactive air surfaces with each other: that is, EHOB versus KinAir (Cobb 1997) and Sofflex versus ROHO (Cooper 1998). We did not pool data from the two studies. We summarised study findings narratively below, and presented key outcome data in Table 3.

**Primary outcomes**

Proportion of participants developing a new pressure ulcer (follow-up duration 7 days and 40 days)

Both studies (223 participants) reported this outcome; see Table 3. Neither study found a difference in the proportions of participants developing a new pressure ulcer between EHOB and KinAir reactive air surface or between Sofflex and ROHO reactive air surface. Evidence is of very low certainty, downgraded once for unclear risk of bias (both studies were at unclear risk of bias in at least one domain), and twice for imprecision: sample sizes were small, there were very few events and both reported CIs crossed RRs = 0.75 and 1.25.

Cobb 1997 (123 participants; follow-up duration 40 days) reported time to pressure ulcer incidence but did not report analysable data. Cobb 1997 reported no statistically significant difference in survival analysis between the two types of reactive air surfaces (EHOB versus KinAir). Evidence is of very low certainty, downgraded once for unclear risk of bias, and twice for imprecision as the sample size was small and there were very few events.

**Secondary outcomes**

Support-surface-associated patient comfort (follow-up duration 7 days)

Only Cooper 1998 (84 complete cases) reported this outcome, defined as the participants' perception of comfort, rated using a 5-point visual rating scale. None of the participants selected 'Very uncomfortable' in either reactive air surface group; five selected 'Uncomfortable' (all using ROHO); eight selected 'Adequate' (four in each group); 48 selected 'Comfortable' (24 in each group), and 23 selected 'Very comfortable' (13 using Sofflex and 10 using ROHO). If we only considered the responses of 'Comfortable' and 'Very comfortable' for this outcome, it is uncertain if there is a difference in the support-surface-associated patient comfort between the two specific reactive air surfaces under evaluation (low-certainty evidence). Evidence certainty was downgraded once for unclear risk of bias and once for imprecision due to the small sample size.

All reported adverse events

Not reported.

Health-related quality of life

Not reported.

Cost-effectiveness

Not reported.

**DISCUSSION**

Summary of main results

We report evidence from 17 RCTs on the effects of reactive air surfaces compared with any support surface on the incidence of pressure ulcers in any population in any setting. We did not analyse data reported in the three studies that compared reactive air surfaces with surfaces that could not be classified. This review had evidence for five comparisons: reactive air surfaces compared with alternating pressure (active) air surfaces, foam surfaces, reactive water surfaces, reactive gel surfaces, and comparisons between two types of reactive air surface (EHOB versus KinAir, and Sofflex versus ROHO). We summarise key findings across these comparisons below.

**Proportion of participants developing a new pressure ulcer**

Five comparisons have evidence for this outcome. However, for most of these comparisons, it is uncertain if there is a difference in the proportions of participants developing a new pressure ulcer between reactive air surfaces and alternating pressure (active) air surfaces (six studies with 1648 participants), reactive water surfaces (one study with 37 participants), reactive gel surfaces (one study with 66 participants), or another type of reactive air surface (two studies with 223 participants). Using reactive air surfaces may reduce the risk of developing new pressure ulcers compared with foam surfaces (four studies with 229 participants; low-certainty evidence).

**Time to pressure ulcer incidence**

Two studies have evidence for this outcome. Low-certainty evidence suggests that people treated with reactive air surfaces are...
at a lower risk of developing a new pressure ulcer than those treated with alternating pressure (active) air surfaces over 14 days’ follow-up in a nursing home setting (one study with 308 participants). However, it is uncertain if there is a difference in the risk of developing new pressure ulcers between two types of reactive air surfaces (one study with 123 participants).

Support-surface-associated patient comfort

This review has evidence on this outcome for three comparisons. It is uncertain if there is a difference in patient comfort responses between reactive air surfaces and foam surfaces on top of an alternating pressure (active) air surface (one study with 72 participants; very low-certainty evidence); and between two types of reactive air surfaces under evaluation (one study with 84 participants; low-certainty evidence). It is uncertain if there is a difference in patient comfort responses between reactive air surfaces and alternating pressure (active) air surfaces (four studies with 1364 participants; very low-certainty evidence).

All reported adverse events

This review has adverse events evidence for one comparison only. It is uncertain if there is a difference in adverse events between reactive air surfaces and foam surfaces (one study with 72 participants; very low-certainty evidence).

Health-related quality of life

This review did not identify evidence for this outcome.

Cost-effectiveness

This review did not include data for this outcome for all five comparisons.

Overall completeness and applicability of evidence

As detailed in Search methods for identification of studies, we ran a comprehensive set of literature searches to maximise the relevant research included here.

The international pressure ulcer guideline recommends considering using a reactive air surface for people at risk for developing pressure ulcers (EPUAP/NPIAP/PPPPIA 2019). Whilst this appears to recommend the applicability of reactive air surfaces for adults and children in any settings, all participants in included studies were adults (with the reported average age ranging from 56 to 87 years, median of 72 years). Across the included studies, more than half (55.2%) of enrolled participants were female. Almost all of enrolled participants (2335/2604; 89.7%) were at (high) risk of pressure ulceration, with risk assessed using a risk assessment tool (e.g. the Braden scale) and most of the 2335 participants (87.1%) were ulcer-free at the time of being recruited. Three included studies (with 302 participants) did include participants with superficial pressure ulcers at baseline.

Most of the included studies were small (half had fewer than 83 participants), whilst eight studies enrolled more than 100 participants, with two enrolling more than 200 participants. These eight studies together accounted for 80.7% (2101/2604) of the participants in this review.

The geographical scope of included studies was limited: almost all the studies were from Europe and North America, and one small study was from China (Jiang 2014).

Included studies recruited participants from a variety of care settings including: acute care settings (seven studies), community and long-term care settings (four studies), or both (two studies); and intensive care units (four studies). Whilst three of the five comparisons included studies from a variety of care settings, due to a limited number of included studies for these comparisons we could not perform pre-specified subgroup analysis by different care settings. Thus, for these three comparisons we are unable to draw conclusions about potential modification of treatment effects in different care settings. Each of the remaining two comparisons only included one study: one was in an intensive care unit and another was in a nursing home. Therefore, their evidence is very limited. These comparisons are reactive air surfaces compared with reactive water surfaces, or reactive gel surfaces. Additionally, there were no data for operating rooms.

We recognise that reactive air surfaces can have a range of other features (e.g. air-fluidised, low-air-loss; see Included studies). In this review, we considered all specific types of reactive air surfaces as generic reactive air surfaces since they have the same underlying mechanism of redistributing pressure activity (i.e. distributing the pressure over a greater area via immersion and envelopment). We did not synthesise evidence for each specific type of reactive air surface.

There were no data for the comparison of reactive air surfaces versus reactive fibre surfaces. Further planned review work using network meta-analysis will add to the findings reported here.

We did not analyse data reported in the three studies that compared reactive air surfaces with undefined surfaces as these comparator group surfaces could not be classified using the NPIAP S3I 2007 support surfaces terms and definitions. However, for completeness of all relevant evidence, we reported the data from these studies in Appendix 4.

Another limitation in the included studies was the large variation in terms of follow-up durations (with a range of five days to six months, median of 14 days). This is partly because different follow-up durations are appropriate in different care settings. For example, patients staying at acute care settings are more likely to be discharged after a short-term hospital stay whilst those staying at community and long-term care settings can have long-term follow-up. The short median duration of follow-up may contribute to an under-estimation of pressure ulcer incidence across study groups of the included studies because most pressure ulcers would occur in the first two to four weeks after hospital admission (Schoonhoven 2007), and some incident pressure ulcers may have been missed in these studies.

Quality of the evidence

We implemented the GRADE approach for assessing the certainty of the evidence and found that most of the included evidence from our 10 meta-analyses or syntheses across five comparisons was of low or very low certainty. Downgrading of evidence was all due to the unclear or high risk of bias of findings, and/or imprecision due to the small numbers of participants, events, wide confidence intervals that failed to exclude important benefits or harms, or all of these.
Limitations in study design
We downgraded once or twice for study limitations for all evidence. We assessed risk of bias according to seven domains: sequence generation, allocation concealment, blinding of participants and personnel, blinding of outcome assessment, selective outcome reporting, incomplete follow-up, and other potential biases. Of the 17 studies, we judged ten as being at unclear overall risk of bias; and seven at high overall risk of bias. The prevalence of high overall risk of bias is partly due to the non-blinding of participants and personnel for most comparisons. We acknowledged that such blinding of participants and personnel is impractical for most comparisons. Therefore, we did not downgrade certainty of evidence for studies at high overall risk of bias that was solely due to the possible presence of performance bias.

Five studies were also at high risk of bias due to unblinded outcome assessment. Unblinded assessment has been found to exaggerate odds ratios (from subjective binary outcomes) by, on average, 36% (Hróbjartsson 2012). The outcome assessment of pressure ulcer incidence is subjective, and blinded assessment - whilst operationally challenging - can be undertaken (e.g. masked adjudication of photographs of pressure areas) (Baumgarten 2009). Therefore, we considered unblinded pressure ulcer incidence assessment could substantially bias effect estimates in the included studies and downgraded the certainty of evidence for detection bias on a study-by-study basis.

Indirectness of evidence
We did not downgrade any result for indirectness of evidence. This was because we considered that the participants, interventions and outcomes in the included studies were within the scope of the published review protocol and there was no indirectness.

Inconsistency of results and unexplained heterogeneity
Statistical heterogeneity was low for nine of the 10 evidence syntheses we performed and we did not downgrade for inconsistency for them. We downgraded for inconsistency for the support-surface-associated patient comfort outcome in the comparison of reactive air surfaces versus alternating pressure (active) air surfaces; and the included studies of this synthesis reported heterogeneous results. The low statistical heterogeneity was partly because seven of the 10 syntheses included only one study. None of the remaining meta-analyses or narrative syntheses included more than six studies. Despite the fact that we found heterogeneity in overall risk of bias, care settings, outcome measurement methods, or follow-up durations between included studies, we considered that heterogeneity (inconsistency) was low and explained, and we decided not to downgrade evidence certainty.

We have to note that although we planned to calculate prediction intervals to understand the implications of heterogeneity, all analyses included a small number (up to six) of included studies which was fewer than the 10 needed for this calculation.

Imprecision of results
We downgraded for imprecision for all pieces of evidence from the 10 evidence syntheses. Study sample sizes were small in most cases (median sample size: 83) with often a small number of events and wide associated confidence intervals around effect estimates. Confidence intervals often crossed the line of null effect, thus meaning we could not discern whether the true population effect was likely to be beneficial or harmful.

Publication bias
We did not downgrade the certainty of evidence for publication bias in all meta-analyses. This is because (1) we have confidence in the comprehensiveness of our literature searches; and (2) we did not find any clear evidence of non-reporting bias of study results. Although we planned to perform funnel plots for meta-analysis to visually inspect for publication bias, there was no analysis including more than ten studies.

Potential biases in the review process
We followed pre-specified methods to review evidence in order to prevent potential bias in the review process. For example, we ran comprehensive electronic searches, searched trials registries and checked the references of systematic reviews identified in electronic searches.

This review also has limitations. Firstly, some included studies may have considered co-interventions as 'usual care' but did not fully describe them. We assumed that all studies had provided co-interventions equally to participants in their study groups if there was nothing to indicate that this was not the case. Secondly, we did not implement pre-specified subgroup analysis as we mentioned above, mainly because no analysis included more than ten studies. Thirdly, the study with time to pressure ulcer data in this review, Beeckman 2019, did not fully report time-to-event data, and the HR and CI we used in Analysis 1.2 were calculated using the methods described in Tierney 2007. We recognise that those calculated data (and associated meta-analyses) might be inaccurate. Fourthly, two studies termed their controls as 'standard hospital surfaces' but did not specify the construction materials of these surfaces. Although we made efforts to collect information on these surfaces, we were not able to classify them. Traditionally, 'standard hospital surfaces' meant foam surfaces, but we felt adopting that assumption was unwarranted. Accurate classification of these surfaces in the future might change the results of some comparisons (e.g. reactive air surfaces versus foam surfaces). Finally, we were not able to pre-specify the comparisons included in this review. This is because specific support surfaces applied could only be known and defined once eligible studies were included. However, we pre-planned to use the NPIAP SSI 2007 support surface terms and definitions to define specific support surfaces in order to avoid any potential bias.

Agreements and disagreements with other studies or reviews
To our knowledge, among the 14 systematic reviews or meta-analyses we identified through electronic searches for this review (Chou 2013; Huang 2013; McGinnis 2011; Mclnnes 2015; Mclnnes 2018; Mistaen 2010a; De Oliveira 2017; Rae 2018; Reddy 2006; Reddy 2008; Serraes 2018; Shi 2018a; Smith 2013; Yao 2018), two recent comprehensive reviews include reactive air surfaces evidence: Shi 2018a, and the Cochrane Review ‘Support surfaces for pressure ulcer prevention’ (Mclnnes 2015).

This review differs from Shi 2018a and Mclnnes 2015 in how specific support surfaces (including reactive air surfaces) are classified and labelled.
As mentioned above, the types of reactive air surfaces used in the included studies varied, and we labelled all these types as a single generic group 'reactive air surfaces'. However, Shi 2018a and McInnes 2015 considered individual types of reactive air surfaces (e.g. air-fluidised bed, low-air-loss hydrotherapy) separately in different comparisons. For example, McInnes 2015 classified support surfaces into 'low-tech' and 'high-tech' groups in general, and included 'static air mattresses' into low-tech 'constant low-pressure devices' but considered low-air-loss surfaces as 'high-tech' regardless of whether they were active or reactive.

Shi 2018a grouped some interventions under the term 'standard hospital surfaces' but concluded that the types of surfaces labelled in this way varied over time, and by setting. We noted that the NPIAP S3I 2007 recommends that the use of 'standard hospital surfaces' term should be avoided and the surface characteristics should be specified. In this review, we made great efforts to define surfaces, where these surfaces were described as a 'standard hospital surface' in the included studies to ensure they were placed in the correct comparisons. We classified those 'standard hospital surfaces' that had no characteristic details or could not be classified using the NPIAP S3I 2007 terms and definitions as undefined surfaces.

The redefinitions and re-classifications of specific support surfaces discussed above can explain some of the inconsistency between these reviews, but importantly, Shi 2018a was a network meta-analysis.

Shi 2018a considered pressure ulcer incidence and support-surface-associated patient comfort outcomes only, whilst this review added adverse effect evidence to the evidence base.

Authors' conclusions

Implications for practice

Using reactive air surfaces may reduce the risk of developing new pressure ulcers within 14 days compared with alternating pressure (active) air surfaces in people in a nursing home setting. Also, the use of reactive air surfaces may reduce pressure ulcer incidence compared with foam surfaces. However, evidence is uncertain about the relative effects of reactive air surfaces versus foam surfaces, reactive water surfaces, reactive gel surfaces, or another type of reactive air surface in preventing pressure ulcers.

Implications for research

Given the large number of different support surfaces available, future studies should prioritise which support surfaces to evaluate on the basis of the priorities of decision-makers. For example, reactive air surfaces versus alternating pressure (active) air surfaces may be a high priority for future evaluation. All interventions used should be clearly described using the current classification system. Researchers should avoid use of some terms, such as 'standard hospital surfaces'. Limitations in included studies are largely due to small sample size and sub-optimal RCT design. The incidence of pressure ulcers can be low in certain settings and this needs to be considered in sample size calculations and when considering the feasibility of trial conduct. Under-recruitment or over-estimation of event rates that then fail to occur, or both, can lead to imprecision and less robust effect estimates.

Future studies should also consider carefully the choice of outcomes they report; time-to-event data for pressure ulcer incidence should be used in trials. Careful and consistent assessment and reporting of adverse events needs to be undertaken to generate meaningful data that can be compared between studies. Likewise, patient comfort is an important outcome but it is poorly defined and reported, and this needs to be considered in future research studies. Further studies should aim to collect and report health-related quality of life using validated measures. Finally, future studies should nest cost-effectiveness analysis in their conduct where possible.

Any future studies must be undertaken to the highest standard possible. Whilst it is challenging to avoid the risk of performance bias in trials of support surfaces as blinding of participants and personnel is seldom possible, stringent protocols - for example, in terms of encouraging consistent care and blinded decision-making - can help to minimise risk. It is also important to fully describe co-interventions (e.g. repositioning) and ensure protocols mandate balanced use of co-interventions across trial arms. The risk of detection bias can also be minimised with the use of digital photography and adjudicators of the photographs being masked to support surfaces (Baumgarten 2009). Follow-up periods should be for as long as possible and clinically relevant in different settings. Where possible and useful, data collection after discharge from acute care settings may be considered.

Acknowledgements

The authors are grateful to the following peer reviewers who provided feedback on both the protocol and the review: Julie Bruce and Zena Moore. Thanks are also due to Jessica Sharp for copy-editing the protocol, to Denise Mitchell for additional copy-edit feedback, to Faith Armitage for copy-editing the review and to Nicole Pitcher for writing the Plain Language Summary.

We also would like to thank Asmara Jammali-Blasi for screening search records; and to thank Zhenmi Liu, Gill Norman and Melanie Stephens for double-checking data extraction and risk of bias assessment for this review. Thanks also to Cochrane Musculoskeletal, Oral, Skin and Sensory Network Editors Peter Tugwell and Jennifer Hilgart for feedback and final approval of the review for publication.

Interventions

Intervention characteristics

Air-fluidised bed

- **Description of interventions**: air-fluidised bed (Clinitron Therapy, Support Systems International, Inc.) … contain ceramic beads … warm, pressurised air is forced up through the beads, on the characteristics of a fluid
- **NPUAP S3I classification**: non-powered, reactive air-fluidised surface
- **Number of participants randomised**: not given
- **Number of participants analysed**: 31
- **Co-interventions**: repositioning every 4 hours without use of other antipressure devices

Conventional therapy

- **Description of interventions**: used a vinyl alternating air-mattress covered by a 19 mm thick foam pad (Lapidus Air Float System, American Pharmaceal Company) on a regular bed
- **NPUAP S3I classification**: non-powered, reactive foam surface plus powered, alternating pressure (active) air surface
- **Number of participants randomised**: not given
- **Number of participants analysed**: 34
- **Co-interventions**: repositioning every 2 hours and elbow or heel pads as needed

Outcomes

Proportion of participants developing a new pressure ulcer

- **Outcome type**: binary
- **Time points**: median 13 days
- **Reporting**: partially reported
- **Measurement method (e.g. scale, self-reporting)**: skin breakdown or epidermal necrosis manifested by eschar over a bony prominence; defined by Shea system; not staged.
- **Definition (including ulcer stage)**: new skin breakdown
- **Dropouts**: 7 withdrawn prior to follow-up and excluded from analysis (6 died, 1 withdrew due to nausea and dislike of the air-fluidised bed).
- **Notes (e.g. other results reported)**: 9 of 31 on air-fluidised beds vs 15 of 34 on conventional therapy (P = 0.24).

Time to pressure ulcer incidence

- **Reporting**: not reported

Support-surface-associated patient comfort

- **Outcome type**: categorical
- **Time points**: median 13 days
- **Reporting**: partially reported
- **Definition and measurement method (e.g. scale, self-reporting)**: patients with change in comfort from baseline. Level of comfort assessed by asking the patient to respond to a second question scored from 1 to 4: “Which of the following best describes the bed you are using here in the hospital: very comfortable, comfortable, uncomfortable, or very uncomfortable?”
- **Dropouts and reasons**: 7 withdrawn prior to follow-up and excluded from analysis (6 died, 1 withdrew due to nausea and dislike of the air-fluidised bed)
- **Data and results**: 8 comfort increased, 4 no change and 1 decreased on air-fluidised bed; 3 increased, 4 no change and 6 decreased on conventional therapy (P = 0.04)
- **Notes (e.g. other results reported)**: All reported adverse events using allocated support surfaces
• **Outcome type:** binary
• **Time points:** median 13 days
• **Reporting:** partially reported
• **Definition and measurement method (e.g. scale, self-reporting):** patients developing complications
• **Dropouts and reasons:** 7 withdrawn prior to follow-up and excluded from analysis (6 died, 1 withdrew due to nausea and dislike of the air-fluidised bed)
• **Data and results:** 8 died, 2 pneumonia, 10 urinary tract infections, 6 hypotension, 5 hypernatraemia, 5 oliguria, 7 sepsis, 16 fever, and 6 heart failure on air-fluidised bed; 7 died, 4 pneumonia, 7 urinary tract infections, 7 hypotension, 5 hypernatraemia, 8 oliguria, 6 sepsis, 22 fever, and 6 heart failure on conventional therapy
• **Notes (e.g. other results reported):** some patients appeared to have multiple adverse events

**Health-related quality of life (HRQOL)**

• **Not reported**

**Cost-effectiveness**

• **Not reported**

**Outcomes that are not considered in this review but reported in trials:**

• Ulcer healing
• Change in total surface area
• Patients improved
• 50% reduction in total surface area
• Pain response

Notes

This is a treatment trial that contains ulcer incidence data.

**Risk of bias**

<table>

**Incomplete outcome data (attrition bias)**

<table>
<thead>
<tr>
<th>All outcomes</th>
<th>Low risk</th>
<th><strong>Outcome group: all outcomes</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>Comment: low risk of bias because of the low rate of attrition (7/72, 9.7%).</td>
</tr>
</tbody>
</table>

**Selective reporting (reporting bias)**

|            | Low risk | **Comment:** the study protocol is not available but it is clear that the published reports include all expected outcomes, including those that were pre-specified. |

**Other bias**

|            | Low risk | **Comment:** the study appears to be free of other sources of bias. |

---

**Study characteristics**

**Methods**

- **Study objective:** to compare the effectiveness and cost of static air support surfaces versus alternating air pressure support surfaces in a nursing home population at high risk for pressure ulcers
- **Study design:** randomised controlled trial
- **Study grouping:** parallel group
- **Duration of follow-up:** 14 days
- **Number of arms:** 2
- **Single centre or multi-sites:** multi-sites
- **Study start date and end date:** April 2017 to May 2018
- **Setting:** nursing home

**Participants**

- **Baseline characteristics**

  - **Inclusion criteria:** (1) high risk of developing pressure ulcer (Braden score 12 and/or Braden subscale score for mobility 2) and/or pressure ulcer category 1; (2) being bed-bound (> 8 h in bed) and/or chair-bound (> 8 h sitting in a chair); (3) aged > 65 years; and (4) use of an alternating air pressure mattress

  - **Exclusion criteria:** (1) nursing home residents with a pressure ulcer category II–IV upon admission; (2) those with an expected length of stay < 2 weeks; (3) those who received end-of-life care; or (4) those with medical contraindications for the use of static air support devices

  - **Sex (M:F):** 71:237 overall; 39:115 in static air support surfaces; 32:122 in alternating air pressure surfaces

  - **Age (years):** mean 87 (SD 7.6) overall; 86.9 (7.9) in static air support surfaces; 86.8 (7.3) in alternating air pressure surfaces

  - **Baseline skin status:** mean Braden score 13 (SD 2.2) overall; all at risk according to the risk score used by the authors

  - **Group difference:** no difference between groups

  - **Total number of participants:** n = 308

  - **Unit of analysis:** individuals

**Interventions**

- **Intervention characteristics**

  - Static air support surfaces
Description of interventions: provided with the static air support surfaces (Repose) ... Repose mattress overlay, Repose1 cushion and Repose1 wedge, or Repose1 foot protector (Frontier Medical Group, South Wales, the UK) ... consist of two urethane multidirectional stretch membranes. The inner membrane is inflated and provides static pressure redistribution throughout the tubular open cells that are oriented along the length of the device. The second membrane is formed from a multidirectional stretch, vapour-permeable material.

NPUP S3I classification: non-powered, reactive air surface
Co-interventions: static air-filled cushion used in 81% of participants and usual seat cushion used in the remaining 19%, static air-filled foot protectors or wedges used in 100% of participants
Number of participants randomised: n = 154
Number of participants analysed: n = 154

Alternating air pressure support surfaces
Description of interventions: all using alternating air pressure support surfaces, with a 3–30 minute cycle time. However, the surfaces were not standardised to reflect current clinical practice.
NPUP S3I classification: powered, alternating pressure (active) air surface
Co-interventions: seat cushions used in 88% and heel protectors used in 34%
Number of participants randomised: n = 154
Number of participants analysed: n = 154

Outcomes
Proportion of participants developing a new pressure ulcer
Outcome type: binary
Time points: 14 days
Reporting: fully reported
Measurement method (e.g. scale, self-reporting): graded using the International Pressure Ulcer Classification system (National Pressure Ulcer Advisory Panel, European Pressure Ulcer Advisory Panel and P.P.P.I.A., 2014)
Definition (including ulcer stage): cumulative incidence and incidence density of the participants developing a new category II-IV pressure ulcer within a 14-day observation period; that is, the percentage of participants in the population at risk who developed a new pressure ulcer
Dropouts: intention-to-treat (ITT) analysis
Notes (e.g. other results reported): 8 of 154 developing category II-IV pressure ulcer in static air support surfaces (6 category II; 2 category III); 18 of 154 in alternating air pressure support surfaces (15 category II; 1 category III; 2 category IV); (Chi² test P = 0.04). Ulcer incidence by areas reported also in the paper but not extracted for this review. Category II - IV ulcer incidence density 0.41/100 observed days (8 ulcers/1970 observed days) (95% CI 0.19 to 0.77) in static air surfaces; 0.89/100 observed days (18 ulcers/2013 observed days) (95% CI 0.55 to 1.39) in alternating air pressure surfaces.

Time to pressure ulcer incidence
Outcome type: binary
Time points: 14 days
Reporting: fully reported
Measurement method (e.g. scale, self-reporting): graded using the International Pressure Ulcer Classification system (National Pressure Ulcer Advisory Panel, European Pressure Ulcer Advisory Panel and P.P.P.I.A., 2014)
Definition (including ulcer stage): median time to develop a new ulcer
Dropouts: median time to develop an ulcer 10.5 days (interquartile range (IQR) 1 to 14) in static air support surfaces; 5.4 (1 to 12) in alternating air pressure support surfaces (Mann-Whitney U test P = 0.05); probability to remain pressure ulcer-free differed between groups (log-rank X² = 4.051, df = 1, P = 0.04); Kaplan–Meier survival plot presented in Fig 2 and HR and 95% CI 0.45 (0.21 to 0.96) estimated by the review authors using the methods described in Tierney 2007.

Support-surface-associated patient comfort
Reporting: not reported
**Beeckman 2019 (Continued)**

All reported adverse events using allocated support surfaces

- **Reporting:** not reported

Health-related quality of life (HRQOL)

- **Reporting:** not reported

Cost-effectiveness

- **Reporting:** not reported
- **Notes:** purchase costs of the support surfaces calculated per participant per day given the 2-year lifespan for a static air mattress and 7-year for an alternating air pressure mattresses. The average lifespan of 2 years for a static air mattress resulted in a daily cost of 0.20 Euro; the average lifespan of 7 years for an alternating air pressure mattress resulted in a daily cost of 0.53 Euro.

**Outcomes that are not considered in this review but reported in trials:**

- None

Bennett 1998

Study characteristics

Methods

- **Study objective:** to determine whether low-air-loss hydrotherapy reduces the incidence of new skin lesions associated with incontinence in hospitalised patients compared with standard care. To assess subjectively patient and nursing satisfaction related to using low-air-loss hydrotherapy beds.
- **Study design:** randomised controlled trial
- **Study grouping:** parallel group
- **Duration of follow-up:** 60 days; median 4 (range 1 to 60) days in low-air-loss hydrotherapy; median 6 (range 1 to 62) days in standard care
- **Number of arms:** 2
- **Single centre or multi-sites:** multi-sites
- **Study start date and end date:** September 1993 to April 1994
- **Setting:** acute and chronic hospital wards

Participants

- **Baseline characteristics**
  - **Inclusion criteria:** (1) incontinence of urine and/or liquid faeces was present; (2) treatment in bed for 16 hours or longer per day was expected; (3) the length of hospitalisation was expected to be 3 or more days; (4) in the opinion of the attending physician, death was not expected within the next 7 days; and (5) no other condition was present, e.g. excessive combativeness or morbid obesity, which, in the opinion of the principal investigator, would preclude the patient from fulfilling the objectives of the project
  - **Exclusion criteria:** those who had a stage III or IV pressure sore if mechanical debridement of the sore was planned or an astringent dressing was ordered
  - **Sex (M:F):** 26:32 in low-air-loss hydrotherapy; 19:39 in standard care
  - **Age (years):** median = 80 years
  - **Baseline skin status:** at high risk, 14 (9 to 28) in low-air-loss hydrotherapy, including 10 individuals with pressure ulcers; at high risk, 15 (8 to 19) in standard care, including 13 with pressure ulcers
  - **Group difference:** no difference
  - **Total number of participants:** 116 individuals
  - **Unit of analysis:** individuals
  - **Unit of randomisation (per patient):** individuals
## Interventions

### Low-air-loss hydrotherapy

- **Description of interventions**: low-air-loss hydrotherapy beds (Clensicair, Support Systems International/Hill-Rom, Charleston, SC) used to maximise the amount of time incontinent patients remain dry; similar to low-air-loss beds e.g. Flexicair therapy beds in which air escapes continuously through the semipermeable fabric used to construct the multiple air cushions of the surface (Bennett 1998); “Model Clensicair; Power needed; Kind - Low air loss with incontinence management system” from product search [http://www.medwow.com/med/alternating-pressure-bed/hill-rom/clensicair/15595.model-spec](http://www.medwow.com/med/alternating-pressure-bed/hill-rom/clensicair/15595.model-spec).
- **NPURAP S3I classification**: powered, reactive low-air-loss air surface
- **Co-interventions**: temperature monitoring every 4 hours
- **Number of participants randomised**: n = 58
- **Number of participants analysed**: n = 42 enrolled for more than 24 hours

### Standard care

- **Description of interventions**: standard care including regular beds, foam mattresses, air mattresses, alternating pressure mattresses, air-fluidised beds, or low-air-loss beds as ordered by physicians
- **NPURAP S3I classification**: standard hospital surface
- **Co-interventions**: not described
- **Number of participants randomised**: n = 58
- **Number of participants analysed**: n = 56 enrolled for more than 24 hours

## Outcomes

**Proportion of participants developing a new pressure ulcer**

- **Outcome type**: binary
- **Time points**: 
- **Reporting**: partially reported
- **Measurement method (e.g. scale, self-reporting)**: 
- **Definition (including ulcer stage)**: the number of participants who developed new stage II to IV pressure ulcers
- **Dropouts**: not described
- **Notes (e.g. other results reported)**: 8 of 42 in low-air-loss hydrotherapy; and 4 of 56 in standard care

**Time to pressure ulcer incidence**

- **Reporting**: not reported

**Support-surface-associated patient comfort**

- **Reporting**: not reported

**All reported adverse events using allocated support surfaces**

- **Reporting**: not reported

**Health-related quality of life (HRQOL)**

- **Reporting**: not reported

**Cost-effectiveness**

- **Reporting**: not reported

**Outcomes that are not considered in this review but reported in trials:**

- Numbers of participants who developed other skin lesions (including chemical irritation, candidiasis, blisters, bruises, abrasions, pressure marks) reported by the type of skin lesions
- Kaplan-Meiers plot for the cumulative development of all truncal skin lesions in the first 9 days
### Bennet 1998 (Continued)

- Temperature on the first study day after enrolment
- Assessment of subjective nursing and patient satisfaction

### Notes

This cannot be regarded as an ulcer healing trial.

### Risk of bias

<table>

### Incomplete outcome data (attrition bias)

**Outcome group: primary outcome**

Comment: high risk of bias because of high proportions of dropouts in both groups and probably using incorrect analysis methods to address missing data.

### Selective reporting (reporting bias)

Comment: the study protocol is not available but it is clear that the published reports include all expected outcomes, including those that were pre-specified.

### Other bias

Comment: the study appears to be free of other sources of bias.

---

### Study characteristics

**Methods**

- **Study objective**: to compare outcomes related to pressure ulcer development when high-risk patients were placed on a KinAir specialty bed, a rented low-air-loss bed, compared to an EHOB Waffle air mattress, a purchased, 1-patient use, static air mattress overlay
  - **Study design**: randomised controlled trial
  - **Study grouping**: parallel group
  - **Duration of follow-up**: 40 days
  - **Number of arms**: 2
  - **Single centre or multi-sites**: single centre
  - **Study start date and end date**: not described
  - **Setting**: all wards and intensive care units (ICU) of a hospital

**Participants**

- **Baseline characteristics**
  - **Inclusion criteria**: over 18 years of age; weighed 290 lb or less; did not have a pre-existing pressure ulcer; were expected to have a length of stay (LOS) of 1 to 2 weeks; determined to be at “high risk” based on the Braden Scale for Predicting Pressure Sore Risk; could speak and read English to provide informed consent
  - **Exclusion criteria**: not described
  - **Sex (M:F)**: 34:27 in EHOB Waffle; 36:26 in KinAir Bed
  - **Age (years)**: overall mean 58; 56 in EHOB Waffle; 60 in KinAir Bed
  - **Baseline skin status**: mean Braden 10.26 (SD 1.61) in EHOB Waffle; 10.02 (1.57) in KinAir. At high risk (Braden score ≤ 12); free of existing ulcers
  - **Group difference**: no difference
  - **Total number of participants**: n = 123
  - **Unit of analysis**: individuals
  - **Unit of randomisation (per patient)**: individuals

**Interventions**

- **Intervention characteristics**
  - EHOB
Cobb 1997 (Continued)

- **Description of interventions**: EHOB Waffle air mattress... a static air mattress overlay ... an air-filled bladder that is placed over a standard hospital mattress
- **NPUAP S3I classification**: non-powered, reactive air surface
- **Co-interventions**: not described
- **Number of participants randomised**: n = 61
- **Number of participants analysed**: n = 61

KinAir

- **Description of interventions**: low-air-loss bed ... a bed in which the standard mattress has been replaced by a series of air filled cushions inflated by a blower motor. Small amounts of air flow through the pores of the cushion fabric to the patient’s skin, keeping it dry.
- **NPUAP S3I classification**: powered, reactive low-air-loss air surface
- **Co-interventions**: not described
- **Number of participants randomised**: n = 62
- **Number of participants analysed**: n = 62

**Outcomes**

**Proportion of participants developing a new pressure ulcer**

- **Outcome type**: binary
- **Time points**: 40 days
- **Reporting**: partially reported
- **Measurement method (e.g. scale, self-reporting)**: assessed using the Shea Staging system, staged from I to IV, based on the degree of tissue damage observed (NPUAP, 1989; Shea, 1975)
- **Definition (including ulcer stage)**: the number of patients developing ulcers of any stage
- **Dropouts**: no missing
- **Notes (e.g. other results reported)**: 20 patients developed pressure ulcers; 12 of 61 (1 stage I and 11 stage II) patients in the EHOB Waffle; 8 of 62 (3 stage I, 3 stage II, and 2 eschar) in KinAir

**Time to pressure ulcer incidence**

- **Outcome type**: time-to-event
- **Time points**: 40 days
- **Reporting**: partially reported
- **Measurement method (e.g. scale, self-reporting)**: see above
- **Definition (including ulcer stage)**: time to pressure ulcer incidence; see above
- **Dropouts**: not described
- **Notes**: the survival plot (Appendix F, Figure 1) "there is no statistically significant difference between the EHOB Waffle mattress or the KinAir bed, although the EHOB survival curve is lower than the KinAir curve"; no further data.

**Support-surface-associated patient comfort**

- **Reporting**: not reported

**All reported adverse events using allocated support surfaces**

- **Reporting**: not reported

**Health-related quality of life (HRQOL)**

- **Reporting**: not reported

**Cost-effectiveness**

- **Reporting**: not reported
- **Notes**: mean costs associated with the pressure reduction surfaces USD 723 (SD 558) in KinAir; USD 49 (33) in EHOB.

**Outcomes that are not considered in this review but reported in trials**
#### Cobb 1997 (Continued)
- Risk factors of pressure ulcer development

**Study objective**: to compare 2 dry-flotation pressure-reducing surfaces in pressure sore incidence, patient comfort and the appropriate use of equipment in 100 orthopaedic patients

**Design**: randomised controlled trial

**Grouping**: parallel group

**Duration of follow-up**: 7 days

**Number of arms**: 2

**Single centre or multi-sites**: single centre

**Study start date and end date**: January to October 1997

**Setting**: 3 emergency trauma orthopaedic wards in a teaching hospital

**Baseline characteristics**

**Inclusion criteria**: “... patients over 65 years of age with no existing pressure damage and a Waterlow risk assessment score of 15 and over”

**Exclusion criteria**: not described

**Sex (M:F)**: 7:44 in Sofflex group; 9:40 in ROHO group

**Age (years)**: mean 83 (SD 7.7) in Sofflex; 83 (7.6) in ROHO

**Baseline skin status**: median Waterlow score 17 (interquartile range (IQR) 15 to 19) in Sofflex; 16 (15 to 18) in ROHO

**Group difference**: no difference

**Total number of participants**: 100

**Unit of analysis**: individuals

**Unit of randomisation (per patient)**: individuals

**Intervention characteristics**

**Sofflex mattress**

- **Description of interventions**: “similar to the ROHO but consists of larger cells ... requires only three sections to make a full mattress ... constructed with flexible interconnecting air cells manufactured from neoprene ... achieve a reduction in interface pressure by the principle of immersion ... immersion increases the surface contact area ... achieved by having a minimal amount of inflation ...”

- **NPUAP S3I classification**: powered, reactive air surface

- **Co-interventions**: ROHO Quatro cushion

- **Number of participants randomised**: n = 51

- **Number of participants analysed**: n = 41

**ROHO mattress**

- **Description of interventions**: "... consisted of four separate sections - three ROHO sections and a foam section for the head ... constructed with flexible interconnecting air cells manufactured from neoprene ... achieve a reduction in interface pressure by the principle of immersion ... immersion increases the surface contact area ... achieved by having a minimal amount of inflation ...”

- **NPUAP S3I classification**: powered, reactive air surface

- **Co-interventions**: ROHO Quatro cushion

- **Number of participants randomised**: n = 49
Number of participants analysed: n = 43

Outcomes

- **Proportion of participants developing a new pressure ulcer**
  - **Outcome type:** binary
  - **Time points:** 7 days
  - **Reporting:** fully reported
  - **Measurement method (e.g. scale, self-reporting):** graded by the Stirling Pressure Sore Severity Scale
  - **Definition (including ulcer stage):** ulcers of any grades
  - **Dropouts:** 10 (4 died, 6 transferred/discharged) in Sofflex; 6 (3 died, 3 transferred/discharged)
  - **Notes (e.g. other results reported):** 3 of 41 individuals in Sofflex (1 grade 1, 1 grade 1.1, 1 grade 2.4); 5 of 43 in ROHO (1 grade 1, 2 grade 1.1, 2 grade 1.2). Of the 8, only 1 had skin breakdown.

Time to pressure ulcer incidence

- **Reporting:** not reported

Support-surface-associated patient comfort

- **Outcome type:** binary
- **Time points:** 7 days
- **Reporting:** fully reported
- **Measurement method (e.g. scale, self-reporting):** 5-point visual rating scale (very uncomfortable, uncomfortable, adequate, comfortable, very comfortable)
- **Definition:** the patients' perception of comfort
- **Dropouts:** 10 (4 died, 6 transferred/discharged) in Sofflex; 6 (3 died, 3 transferred/discharged)
- **Notes:** Sofflex (n = 41) vs ROHO (n = 43); very uncomfortable 0 vs 0; uncomfortable 0 vs 5; adequate 4 vs 4; comfortable 24 vs 24; very comfortable 13 vs 10

**Reactive air surfaces for preventing pressure ulcers (Review)**

Copyright © 2021 The Authors. Cochrane Database of Systematic Reviews published by John Wiley & Sons, Ltd. on behalf of The Cochrane Collaboration.
Inclusion criteria: 18 years or older who were admitted for reconstructive surgery to repair a tissue deficit (full-thickness pressure ulcer involving muscle, fascia and, in some cases, bone) in the sacral-coccygeal, trochanteric or ischial region

Exclusion criteria: unlikely or unwilling to comply with the treatment protocol, which included a minimum of 7 days bed rest within the surgical unit, or unable to consent

Sex (M:F): overall 21:12; 7:8 in alternating therapy; 14:4 in air-fluidised bed

Age (years): mean 56 (range 20 to 80); 62 in alternating therapy; 50 in air-fluidised bed

Baseline skin status: severe full-thickness pressure ulcers

Group difference: not described

Total number of participants: 40 randomised, 33 analysed

Unit of analysis: individuals

Unit of randomisation (per patient): individuals

Interventions

Alternating therapy

- Description of interventions: a specialised alternating therapy support surface (Nimbus 3 Professional, Huntleigh Healthcare LLC). Specialised by means of Vent Valve Technology, not a standard alternating pressure therapy. Single cells to be isolated and permanently deflated beneath the operative site. This deflation completely off-loads the most vulnerable tissue while the mattress continues to deliver optimised cyclic pressure redistribution to other vulnerable areas.
- NPUAP S3I classification: powered, alternating pressure (active) air surface
- Co-interventions: all other care including repositioning, nutrition and continence management in line with the wound centre’s protocol
- Number of participants randomised: n = 19
- Number of participants analysed: n = 15

Air-fluidised bed

- Description of interventions: air-fluidised bed system (Clinitron, Hill-Rom Inc.); “Clinitron® Air Fluidized Therapy beds ... minimizes interface pressure, while maximizing the surface’s immersion and envelopment properties to support healing ... providing statistically lower interface pressure ... Medical grade, silicone-coated bead fluidization promotes a flotation environment” from Hill-Rom website (https://www.hill-rom.com/ca/Products/Products-by-Category/Hospital-Beds-and-Long-Term-Care-Beds/Clinitron-RiteHite-Air-Fluidized-Beds/).
- NPUAP S3I classification: non-powered, reactive air-fluidised surface
- Co-interventions: all other care including repositioning, nutrition and continence management in line with the wound centre’s protocol
- Number of participants randomised: n = 21
- Number of participants analysed: n = 18

Outcomes

Proportion of participants developing a new pressure ulcer

- Outcome type: binary
- Time points: unspecified; hospital stay of 8 days
- Reporting: partially reported
- Measurement method (e.g. scale, self-reporting): assessed by surgical team
- Definition (including ulcer stage): tissue integrity at other vulnerable anatomical locations
- Dropouts: 4 in alternating therapy; 3 in air-fluidised bed (all due to not receiving the allocated intervention)
- Notes (e.g. other results reported): 0 of 15 in alternating therapy; 0 of 18 in air-fluidised bed
Finnegan 2008 (Continued)

Time to pressure ulcer incidence
- **Reporting**: not reported

Support-surface-associated patient comfort
- **Outcome type**: binary
- **Time points**: unspecified; hospital stay of 8 days
- **Reporting**: partially reported
- **Measurement method (e.g. scale, self-reporting)**: self-reported
- **Definition**: subject acceptability - numbers of patients having comfortable response on support surfaces
- **Dropouts**: 4 in alternating therapy; 3 in air-fluidised bed (all due to not receiving the allocated intervention)
- **Notes (e.g. other results reported)**: comfortable: 11 of 15 in alternating therapy; 4 of 18 in air-fluidised bed; uncomfortable: 2 of 15 vs 7 of 18; the rest of patients had no view.

All reported adverse events using allocated support surfaces
- **Reporting**: not reported

Health-related quality of life (HRQOL)
- **Reporting**: not reported

Cost-effectiveness
- **Reporting**: not reported
- **Notes**: cost of support surface provision based on rental costs per day of inpatient care (USD 35/day for alternating therapy; USD 65/day for air-fluidised bed).

Outcomes that are not considered in this review but reported in trials:
- **Integrity of the surgical site**

Notes

**Finnegan 2008 (Continued)**

**Outcome group: comfort outcome**

Comment: unclear risk of bias because it is not specified if patients who reported comfort data were blinded.

| Incomplete outcome data (attrition bias) | Unclear risk |
| All outcomes | Outcome group: all outcomes |

Quote: “four subjects in Group A and three subjects in Group B did not receive the allocated intervention (Fig. 2) and were not included in the follow-up”

Comment: unclear risk of bias because a fair proportion of subjects lost to follow-up.

| Selective reporting (reporting bias) | Low risk |
| Other bias | Low risk |

Comment: the study protocol is not available but it is clear that the published reports include all expected outcomes, including those that were prespecified.

Comment: the study appears to be free of other sources of bias.

---

**Inman 1993**

**Study characteristics**

| Methods | Study objective: to determine, in critically ill patients at risk, both the clinical utility and cost-effectiveness of using an air suspension bed in the prevention of pressure ulcers |
| Study design: randomised controlled trial with cost-effectiveness analysis |
| Study grouping: parallel group |
| Duration of follow-up: mean intensive care unit (ICU) stay 18.8 days (SE 18.1) in air suspension; 15.4 (13.9) in standard ICU bed |
| Number of arms: 2 |
| Single centre or multi-sites: single centre |
| Study start date and end date: March 1989 to November 1990 |
| Setting: intensive care unit of a hospital |

| Participants | Baseline characteristics |
| Inclusion criteria: patients over 17 years of age, had an admission Acute Physiology and Chronic Health Evaluation II (APACHE II) score greater than 15, had an expected stay in the ICU of at least 3 days |
| Exclusion criteria: not described |
| Age (years): mean 63.4 (SE 14.4) in air suspension; 65.4 (13.9) in standard ICU bed |
| Baseline skin status: not described |
| Group difference: no difference in baseline demographics; patients in standard ICU bed had shorter lengths of stay than those in air suspension bed |
| Total number of participants: 100 randomised; 98 completed (neither of the exclusions developed a pressure ulcer during their hospitalisation) |
| Unit of analysis: individuals |

### Outcomes

**Proportion of participants developing a new pressure ulcer**

- **Outcome type:** binary
- **Time points:** not specified
- **Reporting:** partially reported
- **Measurement method (e.g. scale, self-reporting):** measured by research nurses using Shea criteria
- **Definition (including ulcer stage):** the development of pressure ulcers of a severity score greater than 1 graded by Shea criteria
- **Dropouts:** 2 (1 in each group)
- **Notes (e.g. other results reported):** number of patients with ulcers of greater than 1 presented in Figure and WebPlotDigitizer reads: 3 of 49 in air suspension bed; 14 of 49 in standard bed. No. of patients with single ulcer clearly reported: 6 of 49 in air suspension and 25 of 49 in standard bed (this probably included those with erythema). No. of patients with multiple ulcers clearly reported: 1 of 49 in air suspension and 12 of 49 in standard bed

**Time to pressure ulcer incidence**

- **Reporting:** not reported

**Support-surface-associated patient comfort**

- **Reporting:** not reported

**All reported adverse events using allocated support surfaces**

- **Reporting:** not reported

**Health-related quality of life (HRQOL)**

- **Reporting:** not reported

**Cost-effectiveness**

- **Outcome type:** continuous
- **Time points:** not described
- **Reporting:** fully reported
- **Measurement method (e.g. scale, self-reporting):** Cost-effectiveness estimated from a third-party payer’s perspective; effectiveness measured as the number of ICU patients at risk in whom pressure ulcers developed and expressed per 100 patients at risk; cost estimates reported in both US and Canadian 1988 dollars; incremental cost-effectiveness ratio calculated (the cost per pressure ulcer prevented).

- **Notes:** Cost per 100 patients at risk $56,347.40 Canadian dollars in standard bed vs $50,044.80 Canadian dollars in air suspension; cost saved per 100 patients at risk $6302.60 Canadian dollars due to air suspension; pressure ulcers prevented per 100 patients at risk 64 due to air suspension; cost-effectiveness ratio (cost per pressure ulcer prevented) $< 0$ (air suspension bed), meaning air suspension bed was dominant, providing increased effectiveness in the form of fewer pressure ulcers, for less money than the current program of standard ICU bed and frequent patient rotation.

**Outcomes that are not considered in this review but reported in trials:**

- No

Study characteristics

Methods

Study objective: to investigate the efficacy of static low-air-loss mattress (static LALM) and power pressure air mattress (PPAM) in prevention of pressure ulcers

Study design: randomised controlled trial

Study grouping: parallel group

Duration of follow-up: 5 days after surgery

Number of arms: 2

Single centre or multi-sites: multi-sites

Study start date and end date: not described

Setting: hospitals

Participants

Baseline characteristics

Inclusion criteria: age ≥ 18 years; male or female with Braden score ≤ 16 points; general anaesthesia for surgery with operating time ≥ 120 min; admitted to the ICU or surgical wards after surgery; clear consciousness; able to express their feelings correctly; had contraindications for using air mattress (doctor’s orders: lying on hard-bed or flat-bed); completed informed consent and related information

Exclusion criteria: refused to participate in research; in critical condition and repositioning limited by doctor’s orders; using ice blanket; withdrew interventions within 72 h of being offered them; unable to determine the efficacy; incomplete information for the assessment of efficacy or safety outcomes

Sex (M:F): overall 621:453

Age (years): overall mean 57.94 (SD 15.54) years (range 18 to 88)

Baseline skin status: overall mean Braden scores 13.15 (SD 2.25) (range 6 to 17)

Group difference: no difference

Total number of participants: n = 1074

Unit of analysis: individuals

Unit of randomisation (per patient): individuals

Interventions

Intervention characteristics

Static air mattress

- Description of interventions: static air mattress (®WAFFLE static air mattress, EHOB, United States)
- NPIAP S3I classification: non-powered, reactive air surface
- Co-interventions: repositioning every 2 hours
- Number of participants randomised: n = 562
- Number of participants analysed: no data available

Dynamic air mattress

- Description of interventions: dynamic air mattress (Sanma mattress manufacturing factory, Shanghai in China)
- NPIAP S3I classification: powered, alternating pressure (active) air surface
- Co-interventions: repositioning every 2 hours
- Number of participants randomised: n = 512
- Number of participants analysed: no data available
Outcomes

Proportion of participants developing a new pressure ulcer

- **Outcome type**: binary
- **Time points**: not given
- **Reporting**: partially reported
- **Measurement method (e.g. scale, self-reporting)**: graded by the NPIAP 2007 criteria
- **Definition (including ulcer stage)**:
- **Dropouts**: no missing
- **Notes (e.g. other results reported)**: static air mattress group 1.07% (6/562); dynamic air mattress 0.98% (5/512) \(\chi^2 = 0.148, P = 0.882\)

Time to pressure ulcer incidence

- **Not reported**

Support-surface-associated patient comfort

- **Outcome type**: binary
- **Time points**: post-operative 5 days
- **Reporting**: partially reported
- **Measurement method (e.g. scale, self-reporting)**: asking patients’ feelings after using the mattress: 1 = very uncomfortable, 2 = uncomfortable, 3 = just comfortable, 4 = comfortable, 5 = very comfortable
- **Definition**: the level of patients’ comfort
- **Dropouts**: 80 of 562 missing in static air mattress; 100 of 562 missing in dynamic air mattress
- **Notes**: 68 of 482 patients having a comfort level rating more than the median of 4 in static air mattress and 414 of 482 less than the median level; 68 of 462 more than the median level of 4 in dynamic air mattress and 394 less than the median level (\(\chi^2 = 0.071, P = 0.789\))

All reported adverse events using allocated support surfaces

- **Not reported**

Health-related quality of life (HRQOL)

- **Not reported**

Cost-effectiveness

- **Not reported**

Outcomes that are not considered in this review but reported in trials:

None

Unit of analysis: individuals

Unit of randomisation (per patient): individuals

Interventions

**Intervention characteristics**

**SofCare overlay**

- **Description of interventions**: air-filled overlay (SofCare overlay) Gaymar Industries. Additional source of information "Gaymar SofCare air mattress... composed of three distinct layers of more than 300 compensating air cells. The cells are interconnected through a series of air channels. As the cells exchange air, the patient’s weight is redistributed over the entire surface of the cushion... SofCare is unlike any other inflated device... SofCare looks as soft as it feels, “customizing” itself to the body weight and configuration of each individual patient. By conforming to the patient... (http://www.re-habmart.com/pdfs/gaymar_sof_care_overlay_brochure.pdf)"
- **NPIAP S3I classification**: non-powered, reactive air surface
- **Co-interventions**: not described
- **Number of participants randomised**: not described
- **Number of participants analysed**: n = 33

**Gel mattress**

- **Description of interventions**: Gel mattress
- **NPIAP S3I classification**: non-powered, reactive gel surface
- **Co-interventions**: not described
- **Number of participants randomised**: not described
- **Number of participants analysed**: n = 33

Outcomes

**Proportion of participants developing a new pressure ulcer**

- **Outcome type**: binary
- **Time points**: 6 months
- **Reporting**: partially reported
- **Measurement method (e.g. scale, self-reporting)**: not reported
- **Definition (including ulcer stage)**: no. of patients with new ulcers of any grade
- **Dropouts**: specified; but patient flow is not clear enough
- **Notes (e.g. other results reported)**: 10 of 33 in SofCare (5 grade 1 and 5 grade 2); 8 of 33 in Gel mattress (4 grade 1 and 4 grade 2)

**Time to pressure ulcer incidence**

- **Reporting**: not reported

**Support-surface-associated patient comfort**

- **Reporting**: not reported

**All reported adverse events using allocated support surfaces**

- **Reporting**: not reported

**Health-related quality of life (HRQOL)**

- **Reporting**: not reported

**Cost-effectiveness**

- **Reporting**: not reported

**Outcomes that are not considered in this review but reported in trials:**

### Malbrain 2010

#### Study characteristics

**Methods**

**Study objective:** to compare pressure ulcer outcomes in medical intensive care unit (ICU) patients nursed on either a reactive mattress overlay (ROHO®, ROHO Inc, Belleville, IL, USA) or an active alternating pressure mattress (NIMBUS®3, ArjoHuntleigh, Luton Bedfordshire, UK)  

**Study design:** randomised controlled trial
Malbrain 2010 (Continued)

| Study grouping: parallel group |
| Duration of follow-up: not specified; mean study duration reported 12.2 days (SD 5.5) in ROHO and 15 (14) in NIMBUS 3 |
| Number of arms: 2 |
| Single centre or multi-sites: single centre |
| Study start date and end date: not described |
| Setting: medical ICU of a hospital |

**Participants**

**Baseline characteristics**

**Inclusion criteria:** patients admitted to the ICU with a high pressure ulcer risk (Norton score ≤ 8) and requiring mechanical ventilation for an estimated duration of at least 5 days either (a) with intact skin or (b) with pressure ulcers on admission

**Exclusion criteria:** refused to consent to the study; either of 2 mattresses unavailable for patients admitted

**Sex (M:F):** 8:8 across groups; 5:3 in ROHO; 3:5 in NIMBUS 3

**Age (years):** mean 64.7 (SD 15.6) across groups; 71.6 (11.9) in ROHO overlay; 56.9 (16.3) in NIMBUS 3 mattress

**Baseline skin status:** mean Norton score 7.2 (SD 0.7) across groups; 7 (0) in ROHO and 7.4 (1.1) in NIMBUS 3

**Group difference:** different age distributions between groups

**Total number of participants:** n = 16

**Unit of analysis:** individuals

**Unit of randomisation (per patient):** individuals

**Interventions**

**ROHO dry flotation mattress overlay**

- **Description of interventions:** the ROHO DRY FLOTATION mattress overlay (ROHO Inc, Belleville, IL, USA) ... a manually inflatable reactive low-pressure mattress, overlaying a normal hospital mattress that moulds to the body surface in order to distribute the pressure over an area as large as possible.

- **NPIAP S3I classification:** non-powered, reactive air surface

- **Co-interventions:** Belgian consensus protocol for ulcer prevention and treatment (including 2-hourly repositioning)

- **Number of participants randomised:** n = 8

- **Number of participants analysed:** n = 8 assumed

**NIMBUS 3 mattress**

- **Description of interventions:** a fully automatic active alternating pressure mattress replacement consisting of 20 individual cells (3 head, 8 torso, 4 leg and 5 heel) that alternatively inflate and deflate over a 10 min cycle repeatedly off-loading the tissues

- **NPIAP S3I classification:** powered, alternating pressure (active) air surface

- **Co-interventions:** Belgian consensus protocol for ulcer prevention and treatment (including 2-hourly repositioning)

- **Number of participants randomised:** n = 8

- **Number of participants analysed:** n = 8 assumed

**Outcomes**

Proportion of participants developing a new pressure ulcer
Malbrain 2010 (Continued)

- **Outcome type**: binary
- **Time points**: not specified
- **Reporting**: partially reported
- **Measurement method (e.g. scale, self-reporting)**: nurse/clinician-rated ulcers using EPUAP system
- **Definition (including ulcer stage)**: pressure ulcer incidence of stage 1 and incidence of stage 2 to 4 according to EPUAP system
- **Dropouts**: no missing data
- **Notes (e.g. other results reported)**: 3 of 8 individuals (2 stage 3 or 4 and 1 stage 1) in ROHO and 2 of 8 individuals (both stage 1) in NIMBUS 3

**Time to pressure ulcer incidence**
- **Reporting**: not reported

**Support-surface-associated patient comfort**
- **Reporting**: not reported

**All reported adverse events using allocated support surfaces**
- **Reporting**: not reported

**Health-related quality of life (HRQOL)**
- **Reporting**: not reported

**Cost-effectiveness**
- **Reporting**: not reported

**Outcomes that are not considered in this review but reported in trials:**
- Pressure ulcer healing outcome (reported but not extracted because patients with ulcers are not units of randomisation)

### Study characteristics

**Methods**

- **Study objective**: to compare the effects on pressure damage prevalence by using 2 different support systems in patients with fractured neck of femur who were at high risk
- **Study design**: randomised controlled trial
- **Study grouping**: parallel group
- **Duration of follow-up**: post-operation 7 days; post-operation 14 days
- **Number of arms**: 2
- **Single centre or multi-sites**: single centre
- **Study start date and end date**: not described
- **Setting**: hospital ward

**Participants**

- **Baseline characteristics**
  - **Inclusion criteria**: patients with fractured neck of femur [confirmed by X-ray], who were over 60 years old and identified as being 'at very high risk' of developing tissue damage (Medley score > 25)
  - **Exclusion criteria**: not specified
  - **Sex (M:F)**: 11:29 in Repose; 5:35 in NIMBUS II
  - **Age (years)**: mean 83.5 (range 67.3 to 96.2) in Repose and 80.9 (64.4 to 98.4) in NIMBUS II
  - **Baseline skin status**: at very high risk defined by Medley score > 25
  - **Group difference**: no difference
  - **Total number of participants**: 80
  - **Unit of analysis**: individuals
  - **Unit of randomisation (per patient)**: individuals

Interventions

**Repose**

- **Description of interventions**: A low-unit-cost system (Repose) comprising a low-pressure inflatable mattress and cushion that are readily portable and require little maintenance. Manufactured using a special polyurethane material that has a multidirectional stretch, is vapour permeable, waterproof, and x-ray translucent.
- **NPIAP S3I classification**: Non-powered, reactive air surface.
- **Co-interventions**: Standard best practice as appropriate to condition, including regular repositioning.
- **Number of participants randomised**: n = 40
- **Number of participants analysed**: n = 24 at 14-day time point

**NIMBUS II plus Alpha TranCell**

- **Description of interventions**: The system comprised a dynamic flotation mattress (Nimbus II) together with an alternating-pressure cushion for a chair (Alpha TranCell). The alternating pressure cushion is designed for use on a chair or wheelchair.
- **NPIAP S3I classification**: Powered, alternating pressure (active) air surface.
- **Co-interventions**: Standard best practice as appropriate to condition, including regular repositioning.
- **Number of participants randomised**: n = 40
- **Number of participants analysed**: n = 26 at 14-day time point

Outcomes

**Proportion of participants developing a new pressure ulcer**

- **Outcome type**: Binary
- **Time points**: 7 days; 14 days
- **Reporting**: Partially reported
- **Measurement method (e.g. scale, self-reporting)**: Classified as 0 = normal skin; 1 = persistent erythema of the skin; 2 = blister formation; 3 = superficial subcutaneous necrosis; 4 = deep subcutaneous necrosis (not specified which classification system was used).
- **Definition (including ulcer stage)**: No. of patients with a pressure ulcer at any stage [note: not new pressure ulcer incidence].
- **Dropouts**: 16 in Repose and 14 in NIMBUS II plus Alpha TranCell.
- **Notes (e.g. other results reported)**: At 7 days: 6 of 32 in Repose (3 grade 1; 2 grade 2 and 1 grade 3) and 5 of 31 in NIMBUS II (4 grade 1; 1 grade 2 and 0 grade 3); at 14 days: 5 of 24 in Repose (2 grade 1; 0 grade 2 and 3 grade 3) and 4 of 26 in NIMBUS II (2 grade 1; 1 grade 2 and 1 grade 3). Data may not be useful because they are a mixture of new ulcers and pre-existing ulcers not just new ulcers.

**Time to pressure ulcer incidence**

- **Reporting**: Not reported

**Support-surface-associated patient comfort**

- **Outcome type**: Continuous
- **Time points**: 14 days
- **Reporting**: Partially reported
- **Measurement method (e.g. scale, self-reporting)**: Measured using a 100 mm visual analogue scale.
- **Definition**: Not specified what patient comfort is.
- **Dropouts**: 16 in Repose and 14 in NIMBUS II plus Alpha TranCell.
- **Notes**: Mean 67 (SD 18) for 24 individuals in Repose; 60 (25) for 26 individuals in NIMBUS II.

**All reported adverse events using allocated support surfaces**

- **Reporting**: Not reported

**Health-related quality of life (HRQOL)**
### Price 1999 (Continued)

- **Reporting**: not reported

  **Cost-effectiveness**

- **Reporting**: not reported

  **Outcomes that are not considered in this review but reported in trials:**

- No

#### Study characteristics

*Reactive air surfaces for preventing pressure ulcers (Review)*

Copyright © 2021 The Authors. Cochrane Database of Systematic Reviews published by John Wiley & Sons, Ltd. on behalf of The Cochrane Collaboration.
Study objective: to compare the pressure-reducing properties of 3 types of mattress overlays (water, alternating air and static air mattress surfaces) as used with bedbound patients in a clinical setting

Study design: randomised controlled trial

Study grouping: parallel group

Duration of follow-up: mean 10.0 (SD 10.9) days of surgical intensive care unit (SICU) stay in alternating air; 9.4 (8.8) in static air; 8.9 (7.1) in water

Number of arms: 3

Single centre or multi-sites: single centre

Study start date and end date: not described

Setting: 2 surgical ICUs of a hospital

Baseline characteristics

Inclusion criteria: a minimum SICU stay of 48 hr; presence of ventilatory support, or some form of haemodynamic support on admission

Exclusion criteria: those with any evidence of existing skin breakdown upon admission to the SICUs

Sex (M:F): 33:24 across groups

Age (years): mean 67.9 (SD 11.1) in alternating air; 63.6 (18.6) in static air; 66.1 (15.6) in water

Baseline skin status: free of existing skin breakdown

Group difference: no difference

Total number of participants: n = 57

Unit of analysis: individuals

Unit of randomisation (per patient): individuals

Intervention characteristics

Alternating air

• Description of interventions: "a 1.5-in. thick, alternating air mattress, the Lapidus Airfloat System manufactured by the American Hospital Supply Corp., Valencia, CA"

• NPIAP S3I classification: powered, alternating pressure (active) surface

• Co-interventions: not described

• Number of participants randomised: n = 20

• Number of participants analysed: n = 20

Static air

• Description of interventions: "A 4-in. thick static air mattress, the Gaymar Sof Care bed cushion, manufactured by Gaymar Industries Inc., Orchard Park, NY"

• NPIAP S3I classification: non-powered, reactive air surface

• Co-interventions: not described

• Number of participants randomised: n = 20

• Number of participants analysed: n = 20

Water

• Description of interventions: "A 4-in. thick water mattress, the Lotus PXM 3666, manufactured by Connecticut Artcraft Corp., Naugatuck, CT"
Sideranko 1992 (Continued)

- **NPIAP S3I classification**: non-powered, reactive water surface
- **Co-interventions**: not described
- **Number of participants randomised**: n = 17
- **Number of participants analysed**: n = 17

### Outcomes

> **Proportion of participants developing a new pressure ulcer**

- **Outcome type**: binary
- **Time points**: not reported
- **Reporting**: partially reported
- **Measurement method (e.g. scale, self-reporting)**: not reported
- **Definition (including ulcer stage)**: the number of patients developing pressure ulcers
- **Dropouts**: not described; no missing assumed
- **Notes (e.g. other results reported)**: 5 of 20 in alternating air; 1 of 20 in static air; 2 of 17 in water

#### Time to pressure ulcer incidence

- **Reporting**: not reported

#### Support-surface-associated patient comfort

- **Reporting**: not reported

#### All reported adverse events using allocated support surfaces

- **Reporting**: not reported

#### Health-related quality of life (HRQOL)

- **Reporting**: not reported

#### Cost-effectiveness

- **Reporting**: not reported

#### Outcomes that are not considered in this review but reported in trials:

- Interface pressure

Other bias

| Risk | Comment: the study appears to be free of other sources of bias. |

Takala 1996

Study characteristics

Methods

- **Study objective**: to test the hypothesis that this device [a new, easily adjustable antidecubitus mattress] would be clinically effective in the prevention of pressure sores in patients requiring prolonged intensive care
- **Study design**: randomised controlled trial
- **Study grouping**: parallel group
- **Duration of follow-up**: 14 days
- **Number of arms**: 2
- **Single centre or multi-sites**: single centre
- **Study start date and end date**: not described
- **Setting**: intensive care unit (hospital)

Participants

**Baseline characteristics**

- **Inclusion criteria**: non-trauma patients admitted to intensive care unit (ICU) expected to stay > 5 days
- **Exclusion criteria**: patients with accidental injuries
- **Sex (M:F)**: 12:9 in Carital Optima; 13:6 in standard hospital foam mattress
- **Age (years)**: mean 60 (SD 16) in Carital Optima; 63 (12) in standard hospital foam mattress
- **Baseline skin status**: Norton below 8 across groups (high risk)
- **Group difference**: no difference
- **Total number of participants**: n = 40
- **Unit of analysis**: individuals
- **Unit of randomisation (per patient)**: individuals

Interventions

**Intervention characteristics**

Pressure-relieving mattress

- **Description of interventions**: pressure-relieving mattress (Carital Optima, Carital Ltd, Tuusula, Finland). Carital Optima, constant low pressure mattress comprising 21 double air bags on a base, reduce the pressure on the skin by distributing the patient's weight over a maximum contact area. Formed
of the separate upper layer of the cells ... pressure within the upper layer of cells and in the three compartments of the lower layer of cells can be adjusted separately. Additional source of information from Carital-Optima-Brochure-2.pdf (directhealthcaregroup.com) indicates that Carital Optima needs electricity to be functional.

- NPIAP S3I classification: powered, reactive air surface
- Co-interventions: not described
- Number of participants randomised: n = 21
- Number of participants analysed: n = 21

Standard hospital mattress

- Description of interventions: standard hospital mattress (10 cm thick foam mattress, density 35 kg/m3, Espe Inc, Kouvola, Finland)
- NPIAP S3I classification: non-powered, reactive foam surface; high specification (density 35 kg/m3) foam
- Co-interventions: not described
- Number of participants randomised: n = 19
- Number of participants analysed: n = 19

Outcomes

Proportion of participants developing a new pressure ulcer

- Outcome type: binary
- Time points: 14 days
- Reporting: partially reported
- Measurement method (e.g. scale, self-reporting): graded by Shea criteria
- Definition (including ulcer stage): the development of pressure ulcers graded by Shea criteria
- Dropouts: intention-to-treat (ITT) analysis
- Notes (e.g. other results reported): 0 of 21 in pressure-relieving mattress; 7 of 19 in standard hospital mattress (with a totality of 13 ulcers: 9 Shea grade 1A; 4 grade 1B)

Time to pressure ulcer incidence

- Reporting: not reported

Support-surface-associated patient comfort

- Reporting: not reported

All reported adverse events using allocated support surfaces

- Reporting: not reported

Health-related quality of life (HRQOL)

- Reporting: not reported

Cost-effectiveness

- Reporting: not reported

Outcomes that are not considered in this review but reported in trials:

- Interface pressure

Notes

Risk of bias
### Takala 1996 (Continued)

<table>
<thead>
<tr>
<th>Random sequence generation (selection bias)</th>
<th>Unclear risk</th>
<th>Comment: unclear risk of bias because a proper randomisation criteria is unspecified.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Allocation concealment (selection bias)</td>
<td>High risk</td>
<td>Comment: randomisation influenced by mattress availability, therefore, allocation not concealed.</td>
</tr>
</tbody>
</table>
| Blinding of participants and personnel (performance bias) | High risk | **Outcome group: pressure ulcer outcome**

Quote: “Those with an expected ICU stay exceeding five days were randomly assigned to be treated on either…”

Comment: unclear risk of bias because a proper randomisation criteria is unspecified.

| Blinding of outcome assessment (detection bias) | High risk | **Outcome group: pressure ulcer outcome**

Quote: “The study was not blinded, since the severity of illness of the patients precluded their transfer for evaluation of the skin condition by a blinded reviewer, and the type of mattress in the bed could not be blinded”

Comment: high risk of bias because this statement implies blinding of participants and personnel is likely impossible.

| Incomplete outcome data (attrition bias) | Low risk | **Outcome group: pressure ulcer outcome**

Quote: “Sequential analysis of the primary outcome variable (pressure sore formation) on an intention-to-treat basis was done after each block of four patients had completed the treatment”

Comment: low risk of bias because intention-to-treat (ITT) analysis was conducted.

| Selective reporting (reporting bias) | Low risk | Comment: the study protocol is not available but it is clear that the published reports include all expected outcomes, including those that were prespecified. |
| Other bias | Low risk | Comment: the study appears to be free of other sources of bias. |

### Van Leen 2011

#### Study characteristics

- **Study objective:** to evaluate the clinical efficacy of combining a standard 15 cm cold foam mattress with a static air overlay mattress versus a cold foam mattress alone in preventing pressure ulcers
- **Study design:** randomised controlled trial
- **Study grouping:** parallel group
- **Duration of follow-up:** 6 months
- **Number of arms:** 2
- **Single centre or multi-sites:** single centre
- **Study start date and end date:** March 2002 and October 2004
Setting: nursing home

Participants

Baseline characteristics

Inclusion criteria: age > 65, a Norton score between 5-12 and informed consent of the patients or their representatives in case of mental disorders

Exclusion criteria: a pressure ulcer in the previous 6 months

Sex (M:F): 9:33 in static air; 7:34 in cold foam

Age (years): mean 81.1 (SD 8.37) in static air; 83.1 (7.86) in cold foam

Baseline skin status: Norton score presented by subgroups; Norton scale score lower than 12 (lower than 14 = at risk for pressure ulcers) and no existing ulcers

Group difference: more patients in static air having a very low Norton score (i.e. more pressure ulcer prone patients)

Total number of participants: n = 83

Unit of analysis: individuals

Unit of randomisation (per patient): individuals

Interventions

Intervention characteristics

Cold foam mattress

- Description of interventions: standard 15 cm cold foam mattress
- NPIAP S3I classification: non-powered, reactive foam surface
- Co-interventions: standardised the pressure reduction in sitting position by using a static air cushion
- Number of participants randomised: n = 42
- Number of participants analysed: n = 42

Static air overlay

- Description of interventions: a combination of standard 15 cm cold foam mattress with static air overlay
- NPIAP S3I classification: non-powered, reactive air surface
- Co-interventions: standardised the pressure reduction in sitting position by using a static air cushion
- Number of participants randomised: n = 41
- Number of participants analysed: n = 41

Outcomes

Proportion of participants developing a new pressure ulcer

- Outcome type: binary
- Time points: not specified
- Reporting: partially reported
- Measurement method (e.g. scale, self-reporting): pressure ulcers classified by using EPUAP system
- Definition (including ulcer stage): the number of individuals developing a pressure ulcer grade 2, 3 and 4 at the heel or in the sacral/hip region
- Dropouts: not described
- Notes (e.g. other results reported): 2 of 41 in Static air mattress (1 grade 2 and 1 grade 3); 7 of 42 in Cold foam mattress (2 grade 2; and 5 grade 3)

Time to pressure ulcer incidence

- Reporting: not reported

Support-surface-associated patient comfort
Van Leen 2011  (Continued)

- **Reporting**: not reported
  
  *All reported adverse events using allocated support surfaces*

- **Reporting**: not reported
  
  *Health-related quality of life (HRQOL)*

- **Reporting**: not reported
  
  *Cost-effectiveness*

- **Reporting**: not reported

**Outcomes that are not considered in this review but reported in trials:**

- Treatment data on the new ulcers reported but not extracted

### Van Leen 2013

#### Study characteristics

**Reactive air surfaces for preventing pressure ulcers (Review)**
Van Leen 2013 (Continued)

Methods

**Study objective:** to evaluate the clinical efficacy of a combination of a standard 15 cm viscoelastic foam mattress with a static air overlay mattress vs a standard 15 cm visco-elastic foam mattress alone in preventing pressure ulcers

**Study design:** randomised controlled trial

**Study grouping:** cross-over design (data at the first stage extracted)

**Duration of follow-up:** 6 months

**Number of arms:** 2

**Single centre or multi-sites:** single centre

**Study start date and end date:** not described

**Setting:** nursing home

Participants

**Baseline characteristics**

**Inclusion criteria:** age > 65, a Braden score between 6 and 19, and informed consent of the patients or their representatives in case of dementia or other mental disorder

**Exclusion criteria:** patients with an existing pressure ulcer

**Sex (M:F):** 14:6 in static air; 18:3 in foam

**Age (years):** mean 79.1 (no SD) in static air; 80.8 in foam

**Baseline skin status:** at risk and without existing ulcers. Braden scores classified into 2 subgroups and reported accordingly; not extracted

**Group difference:** no difference

**Total number of participants:** n = 41

**Unit of analysis:** individuals

**Unit of randomisation (per patient):** individuals

Interventions

**Intervention characteristics**

Standard visco-elastic foam mattress

- **Description of interventions:** standard visco-elastic foam mattress
- **NPIAP S3I classification:** non-powered, reactive foam surface; visco-elastic foam
- **Co-interventions:** when out of bed, all patients sat on a static air pillow
- **Number of participants randomised:** n = 20
- **Number of participants analysed:** n = 20

Static air overlay

- **Description of interventions:** a combination of a standard visco-elastic foam mattress with a static air overlay
- **NPIAP S3I classification:** non-powered, reactive air surface
- **Co-interventions:** when out of bed, all patients sat on a static air pillow
- **Number of participants randomised:** n = 21
- **Number of participants analysed:** n = 21

Outcomes

**Proportion of participants developing a new pressure ulcer**

- **Outcome type:** binary
- **Time points:** 6 months
Van Leen 2013 (Continued)

- **Reporting**: partially reported
- **Measurement method (e.g. scale, self-reporting)**: not reported; probably measured by the primary investigator
- **Definition (including ulcer stage)**: the development of category 2, 3, or 4 pressure ulcers (PUs) (EPUAP-classification)
- **Dropouts**: no missing
- **Notes (e.g. other results reported)**: 1 of 20 in static air; 3 of 21 in foam

**Time to pressure ulcer incidence**

- **Reporting**: not reported

**Support-surface-associated patient comfort**

- **Reporting**: not reported

**All reported adverse events using allocated support surfaces**

- **Reporting**: not reported

**Health-related quality of life (HRQOL)**

- **Reporting**: not reported

**Cost-effectiveness**

</table>
Vermette 2012 (Continued)

- **Description of interventions**: the rented surfaces used in the study are RIK® and TheraKair® (KCI Medical, San Antonio, TX) ... RIK® overlay ... consists of an microfluid static overlay (MSO) that has no memory foam ... The TheraKair® Visio is a low-air-loss dynamic mattress (LALDM) with pulsation ... 50 patients used an MSO and 5 patients used an LALDM
- **NPIAP S3I classification**: non-powered, reactive surface; undefined in NPIAP S3I & powered, alternating pressure (active) low-air-loss air surface
- **Co-interventions**: identical positioning protocols
- **Number of participants randomised**: n = 55
- **Number of participants analysed**: n = 55

Inflated static overlay

- **Description of interventions**: the Waffle® overlay (EHOB, Indianapolis, IN) is a plastic, inflated static overlay (ISO) that reduces pressure and requires proper inflation (air between the mattress and skin) to optimise prevention of pressure ulcers
- **NPIAP S3I classification**: non-powered, reactive air surface
- **Co-interventions**: identical positioning protocols
- **Number of participants randomised**: n = 55
- **Number of participants analysed**: n = 55

### Outcomes

**Proportion of participants developing a new pressure ulcer**

- **Outcome type**: binary
- **Time points**: 14 days
- **Reporting**: fully reported
- **Measurement method (e.g. scale, self-reporting)**: classified according to the 6 grades of the National Pressure Ulcer Advisory Panel as Stage I, Stage II, Stage III, Stage IV, suspected deep tissue
- **Definition (including ulcer stage)**: the development of a pressure ulcer within the maximum 2-week period of participation
- **Dropouts**: no missing
- **Notes (e.g. other results reported)**: 6 of 55 in MSO or LALDM; 2 of 55 in ISO

**Time to pressure ulcer incidence**

- **Reporting**: not reported

**Support-surface-associated patient comfort**

- **Outcome type**: binary
- **Time points**: not specified
- **Reporting**: partially reported
- **Measurement method (e.g. scale, self-reporting)**: patients-self rated comfort level on a scale of 1 to 5, 1 indicating very comfortable and 5 indicating not comfortable
- **Definition**: the number of subjects with ratings of 1, 2 or 3 (indicating comfort)
- **Dropouts**: 68 expressed opinions regarding comfort
- **Notes**: 27 of 30 in MSO or LALDM, 29 of 34 in ISO

**All reported adverse events using allocated support surfaces**

- **Reporting**: not reported

**Health-related quality of life (HRQOL)**

- **Reporting**: not reported

**Cost-effectiveness**

- **Reporting**: not reported
Notes: total costs associated with the surfaces 16,086 Canadian dollars in MSO or LALDM and 3,364 Canadian dollars in ISO

### Gardner 2008

**Methods**  Randomised controlled trial (two-arm)

**Participants**
- **Inclusion criteria:** patients at risk of pressure injury (Waterlow score > 9)
- **Exclusion criteria:** under 16 years; unable to tolerate extended time lying supine; and with sacral pressure injury of Stage 2 or above.
- **Number of participants:** 66
- **Age:** on average 68 years
- **Gender (M:F):** 34:25
- **Baseline skin status:** at risk of ulcer (Waterlow score > 9), without existing severe ulcers.

**Interventions**
- Airflotation and Ruby mattress
  - **Description of interventions:** an alternating pressure air mattress
  - **NPIAP S3I classification:** powered, alternating pressure, active, air surface
- ComfortPlus mattress
  - **Description of interventions:** unspecified, probably foam surfaces
  - **NPIAP S3I classification:** non-powered, reactive, foam surfaces

**Outcomes**
- **Outcomes of interest to this review:**
  - Unspecified
- **Outcomes unrelated to this review:**
  - Interface pressure

**Notes**

### Henn 2004

**Methods**  Not available

**Participants**  Not available

**Interventions**  Alternating pressure air surfaces and a type of surface that cannot be defined

**Outcomes**  Not available

**Notes**  Unable to obtain its full text

### Knight 1999

**Methods**  Not available

**Participants**  Not available

**Interventions**  Pressure relieving surfaces that cannot be defined

</tbody>
</table>
### Alternative reactive support surfaces (non-foam or air-filled): reactive gel surfaces

| Non-powered reactive gel surfaces | A group of support surfaces made of gel materials, which have a reactive pressure redistribution function, without the requirement for electrical power | Gel mattress, gel pad used in operating theatre |

### Alternative reactive support surfaces (non-foam or air-filled): reactive sheepskin surfaces

| Non-powered reactive sheepskin surfaces | A group of support surfaces made of sheepskin, which have a reactive pressure redistribution function, without the requirement for electrical power | Australian Medical Sheepskins overlay |

### Alternative reactive support surfaces (non-foam or air-filled): reactive water surfaces

| Non-powered reactive water surfaces | A group of support surfaces based on water, which has the capability of a reactive pressure redistribution function, without the requirement for electrical power | Water mattress |

### Alternating pressure (active) air surfaces

| Powered active air surfaces | A group of support surfaces made of air cells, which mechanically alternate the pressure beneath the body to reduce the duration of the applied pressure (mainly via inflating and deflating to alter the contact area between support surfaces and the body) (i.e. alternating pressure, or active, mode), with the requirement for electrical power | Alternating pressure-relieving air mattress (e.g. Nimbus II, Cairwave, Airwave, MicroPulse), large-celled ripple |

| Powered active low-air-loss air surfaces | A group of support surfaces made of air cells, which have the capability of alternating pressure redistribution as well as low-air-loss for drying local skin, with the requirement for electrical power | Alternating pressure low-air-loss air mattress |

| Powered hybrid system air surfaces | A group of support surfaces made of air cells, which offer both reactive and active pressure redistribution modes, with the requirement for electrical power | Foam mattress with dynamic and static modes (e.g. Softform Premier Active) |

| Powered hybrid system low-air-loss air surfaces | A group of support surfaces made of air cells, which offer both reactive and active pressure redistribution modes as well as a low-air-loss function, with the requirement for electrical power | Stand-alone bed unit with alternating pressure, static modes and low air-loss (e.g. TheraPulse) |

### Standard hospital surfaces

| Standard hospital surfaces | Standard hospital surfaces | A group of support surfaces made of any materials, used as-usual in a hospital and without reactive or active pressure redistribution capabilities, nor any other functions (e.g. low-air-loss, or air-fluidised). | Standard hospital (foam) mattress, National Health Service Contract hospital mattress, standard operating theatre surface configuration, standard bed unit and usual care |

Reactive air surfaces for preventing pressure ulcers (Review)
Copyright © 2021 The Authors. Cochrane Database of Systematic Reviews published by John Wiley & Sons, Ltd. on behalf of The Cochrane Collaboration.
Appendix 3. Risk of bias

1 'Risk of bias' assessment in individually randomised controlled trials

1. Was the allocation sequence randomly generated?

Low risk of bias

The study authors describe a random component in the sequence generation process, such as referring to a random number table, using a computer random number generator, coin tossing, shuffling cards or envelopes, throwing dice, drawing of lots.
High risk of bias
The study authors describe a non-random component in the sequence generation process. Usually, the description would involve some systematic, non-random approach, for example, sequence generated by odd or even date of birth, sequence generated by some rule based on date (or day) of admission, sequence generated by some rule based on hospital or clinic record number.

Unclear
Insufficient information about the sequence generation process to permit judgement of low or high risk of bias.

2. Was the treatment allocation adequately concealed?
Low risk of bias
Participants and study authors enrolling participants could not foresee assignment because one of the following, or an equivalent method, was used to conceal allocation: central allocation (including telephone, web-based and pharmacy-controlled randomisation); sequentially numbered drug containers of identical appearance; sequentially numbered, opaque, sealed envelopes.

High risk of bias
Participants or study authors enrolling participants could possibly foresee assignments and thus introduce selection bias, e.g. allocation was based on: using an open random allocation schedule (e.g. a list of random numbers); or assignment envelopes were used without appropriate safeguards (e.g. if envelopes were unsealed or non-opaque or not sequentially numbered), alternation or rotation, date of birth, case record number, any other explicitly unconcealed procedure.

Unclear
Insufficient information to permit judgement of low or high risk of bias. This is usually the case if the method of concealment is not described or not described in sufficient detail to allow a definite judgement, for example if the use of assignment envelopes is described, but it remains unclear whether envelopes were sequentially numbered, opaque and sealed.

3. Blinding: was knowledge of the allocated interventions by participants and personnel adequately prevented during the study?
Low risk of bias
Any one of the following.
• No blinding, but the review authors judge that the outcome is not likely to be influenced by lack of blinding.
• Blinding of participants and key study personnel ensured, and unlikely that the blinding could have been broken.

High risk of bias
Any one of the following.
• No blinding or incomplete blinding, and the outcome is likely to be influenced by lack of blinding.
• Blinding of key study participants and personnel attempted, but likely that the blinding could have been broken.
• Either participants or some key study personnel were not blinded, and the non-blinding of others is likely to introduce bias.

Unclear
Any one of the following.
• Insufficient information to permit a judgement of low or high risk of bias.
• The study did not address this outcome.

4. Blinding: was knowledge of the allocated interventions by outcome assessors adequately prevented during the study?
Low risk of bias
Any one of the following.
• No blinding, but the review authors judge that the outcome measurement is not likely to be influenced by lack of blinding.
• Blinding of outcome assessment ensured, and unlikely that the blinding could have been broken.

High risk of bias
Any one of the following.
• No blinding or incomplete blinding, and the outcome measurement is likely to be influenced by lack of blinding.
• Blinding of outcome assessment attempted, but likely that the blinding could have been broken.
Unclear
Any one of the following.

- Insufficient information to permit a judgement of low or high risk of bias.
- The study did not address this outcome.

5. Were incomplete outcome data adequately addressed?

Low risk of bias
Any one of the following.

- No missing outcome data.
- Reasons for missing outcome data unlikely to be related to true outcome (for survival data, censoring unlikely to be introducing bias).
- Missing outcome data balanced in numbers across intervention groups, with similar reasons for missing data across groups.
- For dichotomous outcome data, the proportion of missing outcomes compared with observed event risk is not sufficient to have a clinically relevant impact on the intervention effect estimate.
- For continuous outcome data, the plausible effect size (difference in means or standardised difference in means) among missing outcomes is not sufficient to have a clinically relevant impact on observed effect size.
- Missing data have been imputed using appropriate methods.

High risk of bias
Any one of the following.

- Reason for missing outcome data is likely to be related to the true outcome, with either imbalance in numbers or reasons for missing data across intervention groups.
- For dichotomous outcome data, the proportion of missing outcomes compared with observed event risk is sufficient to induce clinically relevant bias in intervention effect estimate.
- For continuous outcome data, the plausible effect size (difference in means or standardised difference in means) among missing outcomes is sufficient to induce clinically relevant bias in the observed effect size.
- ‘As-treated’ analysis done, with substantial departure of the intervention received from that assigned at randomisation.
- Potentially inappropriate application of simple imputation.

Unclear
Any one of the following.

- Insufficient reporting of attrition/exclusions to permit judgement of low or high risk of bias (e.g. number randomised not stated; no reasons for missing data provided).
- The study did not address this outcome.

6. Are reports of the study free of suggestion of selective outcome reporting?

Low risk of bias
Any of the following.

- The study protocol is available and all of the study’s prespecified (primary and secondary) outcomes that are of interest in the review have been reported in the prespecified way.
- The study protocol is not available but it is clear that the published reports include all expected outcomes, including those that were prespecified (convincing text of this nature may be uncommon).

High risk of bias
Any one of the following.

- Not all of the study’s prespecified primary outcomes have been reported.
- One or more primary outcomes are reported using measurements, analysis methods or subsets of the data (e.g. subscales) that were not prespecified.
- One or more reported primary outcomes were not prespecified (unless clear justification for their reporting is provided, such as an unexpected adverse effect).
- One or more outcomes of interest in the review are reported incompletely so that they cannot be entered in a meta-analysis.
- The study report fails to include results for a key outcome that would be expected to have been reported for such a study.
Unsure
Insufficient information to permit judgement of low or high risk of bias. It is likely that the majority of studies will fall into this category.

7. Other sources of potential bias

Low risk of bias
The study appears to be free of other sources of bias.

High risk of bias
There is at least one important risk of bias. For example, the study:

- had a potential source of bias related to the specific study design used; or
- has been claimed to have been fraudulent; or
- had some other problem.

Unsure
There may be a risk of bias, but there is either:

- insufficient information to assess whether an important risk of bias exists; or
- insufficient rationale or evidence that an identified problem will introduce bias.

2 'Risk of bias' assessment in cluster-randomised controlled trials (cluster-RCTs)

1. Recruitment bias
Recruitment bias (or identification bias) is the bias that occurs in cluster-RCTs if the personnel recruiting participants know individuals’ allocation, even when the allocation of clusters has been concealed appropriately. The knowledge of the allocation of clusters may lead to bias because the individuals’ recruitment in cluster trials is often behind the clusters’ allocation to different interventions; and the knowledge of allocation can determine whether individuals are recruited selectively.

This bias can be judged through considering the following questions.

- Were all the individual participants identified/recruited before randomisation of clusters?
- Is it likely that selection of participants was affected by knowledge of the intervention?
- Were there baseline imbalances that suggest differential identification or recruitment of individual participants between arms?

2. Baseline imbalance
Baseline imbalance between intervention groups can occur due to chance, problems with randomisation, or identification/recruitment bias. The issue of recruitment bias has been considered above.

In terms of study design, the risk of chance baseline imbalance can be reduced by the use of stratified or pair-matched randomisation. Minimisation — an equivalent technique to randomisation — can be used to achieve better balance in cluster characteristics between intervention groups if there is a small number of clusters.

Concern about the influence of baseline imbalance can be reduced if trials report the baseline comparability of clusters, or statistical adjustment for baseline characteristics.

3. Loss of clusters
Similar with missing outcome data in individually randomised trials, bias can occur if clusters are completely lost from a cluster trial, and are omitted from the analysis.

The amount of missing data, the reasons for missingness and the way of analysing data given the missingness should be considered in assessing the possibility of bias.

4. Incorrect analysis
Data analyses, which do not take the clustering into account, in cluster trials will be incorrect. Such analyses lead to a "unit of analysis error" and over-precise results (overly small standard error) and overly small P values. Though these analyses will not result in biased estimates of effect, they (if not correctly adjusted) will lead to too much weight allocated to cluster trials in a meta-analysis.

Note that the issue of analysis may not lead to concern any more and will not be considered substantial if approximate methods are used by reviewers to address clustering in data analysis.
5. Comparability with individually randomised trials

In the case that a meta-analysis includes, for example, both cluster-randomised and individually randomised trials, potential differences in the intervention effects between different trial designs should be considered. This is because the "contamination" of intervention effects may occur in cluster-randomised trials, which would lead to underestimates of effect. The contamination could be known as a "herd effect", i.e. within clusters, individuals' compliance with using an intervention may be enhanced, which in return affects the estimation of effect.

Appendix 4. Results of studies that were not analysed

<table>
<thead>
<tr>
<th>Outcomes</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>Comparison: Reactive air surfaces compared with undefined surfaces</td>
<td>• Two studies (216 participants) that compared reactive air surfaces with undefined 'standard hospital surfaces' reported inconsistent results: Bennett 1998 (116 participants) suggested no difference in the proportion of participants developing a new ulcer between reactive air surfaces and undefined surfaces (RR 2.00, 95% CI 0.64 to 6.28) whilst Inman 1993 (100 participants) suggested reactive air surfaces reduced the risk of having new pressure ulcers (RR 0.21, 95% CI 0.07 to 0.70). • Vermette 2012 (110 participants) compared reactive air surfaces with alternating pressure (active) air surfaces or RIK® microfluid static overlay (MSO), and reported that: 6 of 55 in MSO or low-air-loss dynamic mattress (LALDM); 2 of 55 in ISO (3.6%) using reactive air surfaces developed a new pressure ulcer and 6 of 55 (10.9%) using undefined reactive surfaces developed new ulcers. The RR is 0.33 (95% CI 0.07 to 1.58).</td>
</tr>
</tbody>
</table>

Support-surface-associated patient comfort (follow-up duration 14 days) | Vermette 2012 (110 participants) compared reactive air surfaces with alternating pressure (active) air surfaces or RIK® microfluid static overlay, and defined this outcome as participants self-rated comfort on a scale of 1 to 5 with 1 indicating very comfortable and 5 indicating not comfortable. In total, 68 participants rated comfort: 27 of 30 participants using undefined reactive surfaces and 29 of 34 using reactive air surfaces responded that they were comfortable or very comfortable. |

Cost-effectiveness (follow-up duration 18.8 days) | Only Inman 1993 (100 participants; compared reactive air surfaces with undefined standard hospital surfaces) reported this outcome but did not express it as the incremental cost per health benefit gained. Inman 1993 reported that, when reactive air surfaces were used, the cost saved per 100 patients at risk was 6302.6 Canadian dollars; pressure ulcers prevented per 100 patients at risk were 64; and therefore, reactive air surfaces dominated standard hospital surfaces. |

**HISTORY**

Protocol first published: Issue 5, 2020
Review first published: Issue 4, 2021

**CONTRIBUTIONS OF AUTHORS**

Chunhu Shi: conceived the review; designed the review; coordinated the review; extracted data; analysed or interpreted data; undertook quality assessment; performed statistical analysis; produced the first draft of the review; contributed to writing or editing the review; approved the final review prior to publication; is guarantor of the review.

Jo Dumville: conceived the review; designed the review; coordinated the review; analysed or interpreted data; checked quality of statistical analysis; produced the first draft of the review; contributed to writing or editing the review; advised on the review; secured funding; performed previous work that was the foundation of the current review; approved the final review prior to publication.

Nicky Cullum: conceived the review; designed the review; coordinated the review; checked quality of data extraction; contributed to writing or editing the review; advised on the review; secured funding; performed previous work that was the foundation of the current review; approved the final review prior to publication.

Sarah Rhodes: conceived the review; designed the review; checked quality of statistical analysis; contributed to writing or editing the review; approved the final review prior to publication.

Vannessa Leung: checked quality of data extraction; checked quality assessment; performed previous work that was the foundation of the current review; approved the final review prior to publication.

Elizabeth McInnes: conceived the review; designed the review; coordinated the review; checked quality of data extraction; checked quality assessment; contributed to writing or editing the review; advised on the review; performed previous work that was the foundation of the current review; approved the final review prior to publication.

**Contributions of the editorial base**

Gill Norman (Editor): edited the protocol; advised on methodology, interpretation and content; approved the final protocol prior to publication.

Gill Rizzello (Managing Editor): coordinated the editorial process; advised on content; edited the protocol and the review.

Sophie Bishop (Information Specialist): designed the search strategy and edited the search methods section.

Tom Patterson (Editorial Assistant): edited the reference sections of the protocol and the review.

**DECLARATIONS OF INTEREST**

Chunhu Shi: I received research funding from the National Institute for Health Research (NIHR) (Research for Patient Benefit, Evidence synthesis for pressure ulcer prevention and treatment, PB-PG-1217-20006). I received support from the Tissue Viability Society to attend conferences unrelated to this work. The Doctoral Scholar Awards Scholarship and Doctoral Academy Conference Support Fund (University of Manchester) also supported a PhD and conference attendance respectively; both were unrelated to this work.

Jo Dumville: I am Chief Investigator on a National Institute for Health Research grant that funded the conduct of this review (Research for Patient Benefit, Evidence synthesis for pressure ulcer prevention and treatment, PB-PG-1217-20006). This research was co-funded by the National Institute for Health Research Manchester Biomedical Research Centre and partly funded by the National Institute for Health Research Applied Research Collaboration Greater Manchester.
Nicky Cullum: I am Co-investigator on a National Institute for Health Research grant that funded the conduct of this review (Research for Patient Benefit, Evidence synthesis for pressure ulcer prevention and treatment, PB-PG-1217-20006). This research was co-funded by the National Institute for Health Research Manchester Biomedical Research Centre, and partly funded by the National Institute for Health Research Applied Research Collaboration Greater Manchester.

My previous and current employers received research grant funding from the NHS Research and Development programme, and subsequently the NIHR, for previous versions of this review. The funders had no role in the conduct of the review. My previous employer received research grant funding from the NIHR for an RCT comparing different alternating pressure air surfaces for pressure ulcer prevention. This RCT (for which I was the Chief Investigator) was not eligible for inclusion in this review.

Sarah Rhodes: my salary is funded from three NIHR grants and a grant from Greater Manchester Cancer.

Vanessa Leung: none known.

Elizabeth McInnes: none known.

SOURCES OF SUPPORT

Internal sources

- Division of Nursing, Midwifery and Social Work, School of Health Sciences, Faculty of Biology, Medicine and Health, University of Manchester, UK

External sources

- National Institute for Health Research, UK

This project is funded by the National Institute for Health Research (NIHR) under its Research for Patient Benefit (RfPB) Programme (Grant Reference Number PB-PG-1217-20006). The views expressed are those of the author(s) and not necessarily those of the NIHR or the Department of Health and Social Care.

- NIHR Manchester Biomedical Research Centre (BRC), UK

This research was co-funded by the NIHR Manchester BRC. The views expressed in this publication are those of the authors and not necessarily those of the NHS, the National Institute for Health Research or the Department of Health and Social Care.

- National Institute for Health Research (NIHR), UK

This project was supported by the National Institute for Health Research, via Cochrane Infrastructure funding to Cochrane Wounds. The views expressed are those of the authors and not necessarily those of the NIHR or the Department of Health and Social Care.

- National Institute for Health Research Applied Research Collaboration (ARC) Greater Manchester, UK

Nicky Cullum and Jo Dumville's work on this project was partially funded by the National Institute for Health Research Applied Research Collaboration Greater Manchester. The views expressed in this publication are those of the authors and not necessarily those of the National Institute of Health Research or the Department of Health and Social Care.

DIFFERENCES BETWEEN PROTOCOL AND REVIEW

- Two review authors independently assessed the titles and abstracts of the new search results for relevance using Rayyan rather than using Covidence.

- For new included studies, one review author independently extracted data and another review author checked all data, rather two review authors independently carrying out data extraction.

- When a study only had complete case data, we considered complete case data in the related main analysis (i.e. assuming no missing data issue). This was not pre-planned.

- We presented separate 'Summary of findings' tables for four of the five comparisons evaluated in this review. We did not present the table for the comparison between different types of reactive air surfaces.

- Where we did not pool data, we conducted a GRADE assessment and presented these assessments in a narrative format in 'Summary of findings' tables. This was not pre-planned.
