

**Proceedings of the
20th Annual Conference on
Research in Undergraduate
Mathematics Education**

Editors:

Aaron Weinberg

Chris Rasmussen

Jeffrey Rabin

Megan Wawro

Stacy Brown

San Diego, California

February 23-25, 2017

Presented by

The Special Interest Group of the Mathematical Association of America
(SIGMAA) for Research in Undergraduate Mathematics Education

CITATION: In (Eds.) A. Weinberg, C. Rasmussen, J. Rabin, M. Wawro, and S. Brown, Proceedings of the 20th Annual Conference on Research in Undergraduate Mathematics Education, San Diego, California. (ISSN 2474-9346).

Table of Contents

Best Paper Award	
Leveraging real analysis to foster pedagogical practices	1
<i>Nicholas Wasserman, Keith Weber and William McGuffey</i>	
Honorable Mention	
Students' epistemological frames and their interpretation of lectures in advanced mathematics	16
<i>Victoria Krupnik, Keith Weber and Tim Fukawa-Connelly</i>	
Meritorious Citation	
Set-based meanings for the truth of conditionals: A case study and a framework	31
<i>Alec Hub and Paul Dawkins</i>	
Pre-journal Award	
A new methodological approach for examining mathematical knowledge for teaching at the undergraduate level: Utilizing task unfolding and cognitive demand	39
<i>Erica Miller</i>	
Conference Papers	
Mathematical actions, mathematical objects, and mathematical induction	53
<i>Rachel Arnold and Anderson Norton</i>	
Examining students' procedural and conceptual understanding of eigenvectors and eigenvalues in the context of inquiry-oriented instruction	67
<i>Khalid Bouhjar, Christine Andrews-Larson, Muhammad Haidar and Michelle Zandieh</i>	
Students' understanding of test statistics in hypothesis testing	82
<i>Annie Childers, Darryl Chamberlain Jr., Aubrey Kemp, Leslie Meadows, Harrison Stalvey and Draga Vidakovic</i>	
The role of visual reasoning in evaluating statements about real-valued functions: A comparison of two advanced calculus students	93
<i>Erika David, Kyeong Hah Roh and Morgan Sellers</i>	
Conceptual understanding of differential calculus: A comparative study	108
<i>Daria Gerasimova, Kathleen Matson, Robert Sachs and Margret Hjalmarson</i>	
Students ways of thinking in a traditional and inquiry-based linear algebra course	116
<i>Sarah Hough, Monica Mendoza and Elizabeth Thoren</i>	
Data cleaning in mathematics education research: The overlooked methodological step	129
<i>Aleata Hubbard</i>	
Mathematicians' evaluations of the language of mathematical proof writing at the undergraduate level in three different pedagogical contexts	141
<i>Kristen Lew and Juan Pablo Mejia-Ramos</i>	

Spatial training and calculus ability: Investigating impacts on student performance and cognitive style	156
<i>Lindsay McCunn and Emily Cilli-Turner</i>	
Exploring student conceptions of binary operation	166
<i>Kathleen Melhuish and Joshua Fagan</i>	
Opportunities to learn from teaching: A case study of two graduate teaching assistants	181
<i>Erica Miller, Nathan Wakefield and Yvonne Lai</i>	
Learning to notice and use student thinking in undergraduate mathematics courses	195
<i>Anna Pascoe, Shari L. Stockero</i>	
Student conceptions of three-dimensional solids	209
<i>Stepan Paul and Monica Mendoza</i>	
Student mathematical connections in an introductory linear algebra course	221
<i>Spencer Payton</i>	
The effects of the epsilon-N relationship on convergence of functions	236
<i>Zackery Reed</i>	
Hypophora: Why take the derivative? (no pause) Because it is the rate	249
<i>Kitty Roach</i>	
Students' conceptions of mappings in abstract algebra	259
<i>Rachel Rupnow and Márcia M. F. Pinto</i>	
Emerging insights from the evolving framework of structural abstraction	274
<i>Thorsten Scheiner</i>	
A comparison of calculus, transition-to-proof, and advanced calculus student quantifications in complex mathematical statements	285
<i>Morgan Sellers, Kyeong Hah Roh and Erika David</i>	
Exploring undergraduates' experience of the transition to proof	298
<i>John Smith, Mariana Levin, Younggon Bae, V. Satyam and Kevin Voogt</i>	
Knowledge about student understanding of eigentheory: Information gained from multiple choice extended assessment	311
<i>Kevin Watson, Megan Wawro, Sarah Kerrigan and Michelle Zandieh</i>	
Meta-representational competence with linear algebra in quantum mechanics	326
<i>Megan Wawro, Kevin Watson and Warren Christensen</i>	
Corequisite remediation and math pathways in Oklahoma	338
<i>Matthew Wilson and Michael Oehrtman</i>	
Using intuitive examples from women of color to reveal nuances about basis	346
<i>Aditya Adiredja and Michelle Zandieh</i>	
Exploration of the factors that support learning: Web-based activity and testing systems in community college algebra	360
<i>Shandy Hawk and Bryan Matlen</i>	
"Explanatory" talk in mathematics research papers	373
<i>Juan Pablo Mejia-Ramos and Matthew Inglis</i>	

How limit can be embodied and arithmetized: A critique of Lakoff and Núñez	383
<i>Timothy Boester</i>	
Alice slowly develops self-efficacy with writing proof frameworks, but her initial progress and sense of self-efficacy evaporates when she encounters unfamiliar concepts: However, it eventually returns . . .	398
<i>Annie Selden, John Selden and Ahmed Benkhalti</i>	
Questioning assumptions about the measurability of subdomains of mathematical knowledge for teaching	413
<i>Heather Howell, Yvonne Lai and Heejoo Suh</i>	
Those who teach the teachers: Knowledge growth in teaching for mathematics teacher educators	428
<i>Shandy Hawk, Billy Jackson and Jenq-Jong Tsay</i>	
Raising reasoning through revision: A case study of an inquiry-based college geometry course	440
<i>Janessa Beach and Rebecca Dibbs</i>	
Developing student understanding: The case of proof by contradiction	454
<i>Darryl Chamberlain Jr. and Draga Vidakovic</i>	
Contributed Reports	
Using women of color’s intuitive examples to reveal nuances about basis	469
<i>Aditya Adiredja and Michelle Zandieh</i>	
Comparing expert and learner mathematical language: A corpus linguistics approach	478
<i>Lara Alcock, Matthew Inglis, Kristen Lew, Juan Pablo Mejia-Ramos, Paolo Rago and Chris Sangwin</i>	
Mathematics instruction leadership in undergraduate departments	485
<i>Naneh Apkarian and Chris Rasmussen</i>	
Using learning trajectories to structure teacher preparation in statistics	494
<i>Anna Bargagliotti and Celia Anderson Rosseau</i>	
Interaction, activities, & feedback: A taxonomy of GTA professional development	502
<i>Daniel Bragdon, Jess Ellis and Jessica Gehrtz</i>	
Difficult dialogs about degenerate cases: A proof script study	511
<i>Stacy Brown</i>	
Stages of development for the concept of inverse in abstract algebra	520
<i>John Paul Cook and Rosaura Uscanga</i>	
Characterizing the nature of introduction to proof courses: A survey of R1 and R2 institutions across the US	528
<i>Erika David and Dov Zazkis</i>	
The role of visual reasoning in evaluating complex mathematical statements: A comparison of two advanced calculus students	536
<i>Erika David, Kyeong Hah Roh, Morgan Sellers and Kody D’Amours</i>	
Features of explanatory proofs: An exploratory study	545
<i>Eyob Demeke</i>	
Undergraduate students’ holistic comprehension of a proof	554
<i>Eyob Demeke</i>	

Generalising univalence from single to multivariable settings: The case of Kyle	562
<i>Allison Dorko</i>	
SCNI: A robust technique to investigate small-group learning at college	570
<i>Fady El Chidiac</i>	
Infinitesimals-based registers for reasoning with definite integrals	579
<i>Rob Ely</i>	
Students' attitudes toward listing and subsequent behavior solving counting problems	588
<i>Sarah Erickson</i>	
Tinker Bell's pixie dust: Exploring the role of differentiation in emergent shape thinking	596
<i>Kristin Frank</i>	
Gender and discipline specific differences in mathematical self-efficacy of incoming students at a large public university	605
<i>Ulrike Genschel and Xuan Hien Nguyen</i>	
Exploring a pre-service teacher's conceptions of area and area units	613
<i>Sayonita Ghosh Hajra and Betsy McNeal</i>	
Contextualizing symbols in word problems	621
<i>Sayonita Ghosh Hajra and Victoria Kofman</i>	
Using oral presentations and cooperative discussions to facilitate learning statistics	629
<i>Abeer Hasan and Sayonita Ghosh Hajra</i>	
Exploration of the factors that support earning: Web-based activity and testing systems in community college algebra	638
<i>Shandy Hawk, Bryan Matlen and Larry Thomas</i>	
Supporting instructional change in mathematics: The role of online and in-person communities	646
<i>Charles Hayward and Sandra Laursen</i>	
Student proficiency with transformational geometry after a college proof-based geometry class	655
<i>Meredith Hegg and Tim Fukawa-Connelly</i>	
Exploring experts' covariational reasoning	664
<i>Natalie Hobson and Kevin Moore</i>	
How students interpret line and vector integral expressions: Domains, integrands, differentials, and outputs	673
<i>Steven Jones and Omar Naranjo</i>	
Definite integrals versus indefinite integrals: How do students see them as the same or as different?	682
<i>Steven Jones and Cache Thompson</i>	
Using video in online work groups to support faculty collaboration	690
<i>Karen Keene, Nicholas Fortune and William Hall</i>	
Undergraduate abstract algebra: Is teaching different at 'teaching' colleges?	698
<i>Rachel Keller, Estrella Johnson, Valerie Peterson and Tim Fukawa Connelly</i>	

Mathematicians’ evaluations of the language of mathematical proof writing at the undergraduate level in three different pedagogical contexts	707
<i>Kristen Lew and Juan Pablo Mejia-Ramos</i>	
An unexpected outcome: Students’ focus on order in the Multiplication Principle	715
<i>Elise Lockwood and Branwen Schaub</i>	
Computational thinking in and for undergraduate mathematics: Perspectives of a mathematician . . .	723
<i>Miroslav Lovric and Ami Mamolo</i>	
“Explanatory” talk in mathematics research papers	732
<i>Juan Pablo Mejia-Ramos and Matthew Inglis</i>	
Managing tensions within a coordinated inquiry-based learning linear algebra course: The role of worksheets	739
<i>Vilma Mesa, Mollee Shultz and Ashley Jackson</i>	
Function sameness to “function” meaning	747
<i>Alison Mirin</i>	
Students’ quantitative reasoning in a revenue maximization context	755
<i>Theminkosi Mkhathshwa and Helen Doerr</i>	
Preservice secondary teachers’ abilities to transfer from graphical to algebraic representations of functions	763
<i>Kyunghee Moon</i>	
Preservice secondary teachers’ abilities to use representations and realistic tasks	771
<i>Kyunghee Moon</i>	
Preservice elementary teachers’ understandings of greatest common factor versus least common multiple	779
<i>Kristin Noblet</i>	
Examining lecturer’s questioning in advanced proof-oriented mathematics classes	787
<i>Teo Paoletti, Victoria Krupnik, Dimitri Papadopoulos, Joseph Olsen, Tim Fukawa-Connelly and Keith Weber</i>	
Transitioning to proof with worked examples	796
<i>Dimitri Papadopoulos</i>	
Approaches to the derivative in Korean and the U.S. calculus classrooms	804
<i>Jungeun Park</i>	
Learning to notice and use student thinking in undergraduate mathematics courses	812
<i>Anna Pascoe and Shari Stockero</i>	
Attention to detail: Norms for proof evaluation in a summer mathematics program	821
<i>Cody Patterson and Xiaowen Cui</i>	
Student mathematical connections in an introductory linear algebra course	829
<i>Spencer Payton</i>	
Mathematicians’ collaborative silences	837
<i>Matthew Petersen</i>	

Graduate student instructors learning from peer observations	846
<i>Daniel Reinholz</i>	
McNuggets, bunnies, and remainders, oh my!	855
<i>Nina Rocha and Jennifer Zakotnik</i>	
Students' conceptions of mappings in abstract algebra	863
<i>Rachel Rupnow</i>	
A success factor model for calculus: The relative impact of and connections between factors affecting student success in college calculus	871
<i>Megan Ryals and Karen Keene</i>	
CxN: Investigating the creative proving process using neuroscience methods	879
<i>Milos Savic, David Plaxco, Michael Wenger, Emily Cilli-Turner, Gail Tang, Houssein El Turkey and Gulden Karakok</i>	
Emerging insights from the evolving framework of structural abstraction in knowing and learning advanced mathematics	886
<i>Thorsten Scheiner and Márcia Pinto</i>	
Physics students' use of symbolic forms when constructing differential elements in multivariable coordinate systems	895
<i>Benjamin Schermerhorn and John Thompson</i>	
A comparison of calculus, transition-to-proof, and advanced calculus student quantifications in complex mathematical statements	903
<i>Morgan Sellers, Kyeong Hah Roh, Erika David and Kody D'Amours</i>	
Beyond the product structure for definite integrals	912
<i>Courtney Simmons and Michael Oehrtman</i>	
Exploring undergraduates' experience of the transition to proof	920
<i>John Smith, Mariana Levin, Younggon Bae and V. Satyam</i>	
Principles for designing tasks that promote covariational reasoning	928
<i>Irma Stevens, Teo Paoletti, Kevin Moore, Biyao Liang and Hamilton Hardison</i>	
Common algebraic errors in calculus courses	937
<i>Sepideh Stewart and Stacy Reeder</i>	
Completeness and convergence: Interdependent development in the context of proving the Intermediate Value Theorem	945
<i>Stephen Strand</i>	
Angle measure, quantitative reasoning, and instructional coherence: The case of David	954
<i>Michael Tallman</i>	
Virtual manipulatives, vertical number lines, and Taylor series convergence: The case of Cody	963
<i>Matthew Thomas and Jason Martin</i>	
Developing students' reasoning about the derivative of complex-valued functions with the aid of Geometer's Sketchpad (GSP)	972
<i>Jonathan Troup</i>	

Calculus students' reasoning about slope as a ratio-of-totals and its impact on their reasoning about derivative	982
<i>Jen Tyne</i>	
Students' understanding of vectors and cross products: Results from a series of visualization tasks ...	991
<i>Monica VanDieren, Deborah Moore-Russo, Jill Wilsey and Paul Seeburger</i>	
Variations in precalculus through Calculus 2 courses	1001
<i>Matthew Voigt, Chris Rasmussen and Naneh Apkarian</i>	
Using expectancy value theory to account for students' mathematical justifications	1009
<i>Keith Weber, Kristen Lew and Juan Pablo Mejía a-Ramos</i>	
Expert vs. novice reading of a calculus textbook: A case study comparison	1018
<i>Emilie Wiesner, Aaron Weinberg, John Barr and Kikki Upham</i>	
Mentor professional development for mathematics graduate student instructors	1026
<i>Sean Yee and Kimberly Rogers</i>	
Order of operations: A case of mathematical knowledge-in-use	1035
<i>Rina Zazkis</i>	

Theoretical Reports

Can/should students learn mathematics theory-building?	1043
<i>Hyman Bass</i>	
How limit can be embodied and arithmetized: A critique of Lakoff and Núñez	1051
<i>Timothy Boester</i>	
Those who teach the teachers: Knowledge growth in teaching for mathematics teacher educators ...	1060
<i>Shandy Hauk, Billy Jackson and Jenq-Jong Tsay</i>	
Research in courses before calculus through the lens of social justice	1068

Emerging Insights from the Evolving Framework of Structural Abstraction

Thorsten Scheiner
University of Hamburg, Germany

Márcia M. F. Pinto
Federal University of Rio de Janeiro, Brazil

Only recently ‘abstraction from objects’ has attracted attention in the literature as a form of abstraction that has the potential to take account of the complexity of students’ knowing and learning processes compatible with their strategy of giving meaning. This paper draws attention to several emerging insights from the evolving framework of structural abstraction in students’ knowing and learning of the limit concept of a sequence. Particular ideas are accentuated that we need to understand from a theoretical point of view since they reveal a new way of understanding knowing and learning advanced mathematical concepts.

Keywords: Limit Concept; Mathematical Cognition; Sense-Making; Structural Abstraction

Introduction

Theoretical and empirical research shows the existence of differences in knowing and learning concerning different kinds of knowledge (diSessa, 2002). A general framework on abstraction cannot encompass the whole complexity of knowing and learning processes in mathematics. Rather, in investigating the nature, form, and emergence of knowledge pieces, various local learning theories may be developed, which will be quite specific to particular mathematical concepts, individuals, and their respective sense-making strategies. As a consequence, the complexity of knowing and learning processes in mathematics cannot be described or explained by only one framework. Instead, we acknowledge that comprehensive understanding of cognition and learning in mathematics draws on a variety of theoretical frameworks on abstraction.

The literature demonstrates significant theoretical and empirical advancement in understanding ‘abstraction-from-actions’ approaches, particularly the cognitive processes of forming a (structural) concept from an (operational) process (Dubinsky, 1991; Gray & Tall, 1994; Sfard, 1991). Abstraction-from-actions approaches take account of a certain sense-making strategy, namely what Pinto (1998) described as ‘extracting meaning’. However, only recently ‘abstraction from objects’ has attracted attention as a form of abstraction that provides a new way of seeing the complexity of knowing and learning processes compatible with students’ strategy of what Pinto (1998) described as ‘giving meaning’.

The purpose of this paper is to provide deeper meaning to a recently evolving framework of a particular kind of ‘abstraction from objects’: structural abstraction. The structural abstraction framework is evolving in the sense that the framework functions both as a tool for research and as an object of research (Scheiner & Pinto, 2016b). In more detail, we use the structural abstraction framework retrospectively as a lens through which we reinterpret a set of findings on students’ knowing and learning of the limit concept of a sequence. This reinterpretation is an active one in the sense that the framework serves as a tool to analyze a set of data, while the framework is also refined and extended since the reinterpretation produces deeper insights about the framework itself. Especially, these more profound insights are what we need to understand from a theoretical point of view since they have relevance for significant issues in knowing and learning advanced mathematical concepts. Such a dynamic view that is aligned with an interpretative approach seems to be promising in responding to questions that evolve while the object of consideration is still under investigation.

We begin by providing an upshot of our synthesis of the literature on abstraction in knowing and learning mathematics. Our synthesis is to suggest an orientation toward the evolving framework of structural abstraction as an avenue to take account of an important area for consideration – that is, drawing attention to the complex knowing and learning processes compatible with students’ ‘giving meaning’ strategy. The structural abstraction framework constitutes the foundation of the second part of the paper providing emerging insights in knowing and learning the limit concept of a sequence. These insights offer theoretical advancement of the framework and deepen our understanding of knowing and learning advanced mathematics.

Mapping the Terrain of Research on Abstraction in Mathematics Education

Abstraction seems to have gained a bad reputation after been questioned by the situated cognition (or situated learning) paradigm, and, as a consequence, has almost disappeared from recent research discourse. This criticism rests primarily on traditional approaches on knowledge transfer through abstraction that led to an understanding of abstraction as a process of decontextualization and a confusion of abstraction with generalization. The recent contribution by Fuchs et al. (2003) shows that such classical approaches to abstraction still exist:

“To abstract a principle is to identify a generic quality or pattern across instances of the principle. In formulating an abstraction, an individual deletes details across exemplars, which are irrelevant to the abstract category [...]. These abstractions [...] avoid contextual specificity so they can be applied to other instances or across situations.” (p. 294)

Though various images of abstraction in the mathematics education literature can be identified (see Scheiner & Pinto, 2016a), several scholars argued against the image of abstraction as decontextualization. Van Oers (1998, 2001), for instance, argued that removing context must impoverish a concept rather than enrich it. Several other scholars have reconsidered and advanced our understanding of abstraction in ways that account for the situated nature of knowing and learning in mathematics. Noss and Hoyles (1996) introduced the notion of *situated abstraction* to describe “how learners construct mathematical ideas by drawing on the webbing of a particular setting which, in turn, shapes the way the ideas are expressed” (p. 122). Webbing in this sense means “the presence of a structure that learners can draw up and reconstruct for support – in ways that they can choose as appropriate for their struggle to construct meaning for some mathematics (Noss & Hoyles, 1996, p. 108). Hershkowitz, Schwarz, and Dreyfus (2001) introduced the notion of *abstraction in context* that they presented as “an activity of vertically reorganizing previously constructed mathematics into new mathematical structure” (p. 202). They identify abstraction in context with what Treffers (1987) described as ‘vertical mathematization’ and propose entire mathematical activity as the unity of analysis. These contributions demonstrate that research on abstraction in knowing and learning mathematics has made significant progress in taking account of the context-sensitivity of knowledge.

Several other contributions shape the territory in mathematics education research on abstraction. Mitchelmore and White (2004) indicate a distinction between abstraction in mathematics and abstraction in mathematics learning. They proposed to include a new meaning in the later, which seemed to be missing in the debate on the notion of abstraction, related to “formation of concepts by empirical abstraction from physical and social experience” (p. 329). Articulated to this understanding, Scheiner (2016) proposed a distinction between two forms of abstraction, namely *abstraction from actions* and

abstraction from objects. This distinction has been further refined in Scheiner and Pinto (2014) arguing that the focus of attention of each form of abstraction takes place on physical objects (referring to the real world) or mental objects (referring to the thought world) (see Fig. 1).

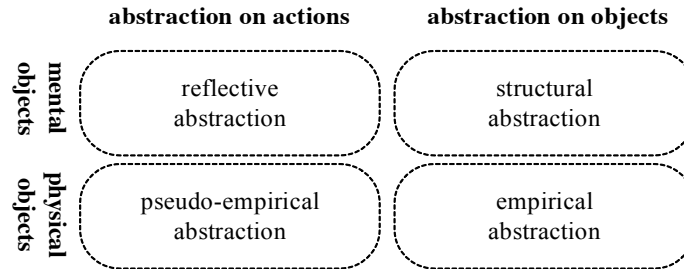

Fig. 1: A frame to capture various kinds of abstraction (reproduced from Scheiner & Pinto, 2014)

We consider this distinction as being productive in trying to capture some of the variety of images of abstraction in mathematics education (for details see Scheiner & Pinto, 2016a). It acknowledges Piaget's (1977/2001) three kinds of abstraction, including pseudo-empirical abstraction, empirical abstraction, and reflective abstraction, that served as critical points of departure in thinking about abstraction in learning mathematics. Research on abstraction in mathematics has long moved beyond classifying and categorizing approaches in cognition and learning, based on similarities of the individuals constructs. For instance, Mitchelmore and White (2007), in going beyond Piaget's empirical abstraction and in drawing on Skemp's (1986) conception of abstraction, described abstraction in learning elementary mathematics concerning seeing the underlying structure rather than the superficial characteristics. Abstraction in learning advanced mathematics, however, is almost always defined in terms of *encapsulation* (or *reification*) of processes into objects, originating in Piaget's (1977/2001) idea of *reflective abstraction*. Reflective abstraction is an abstraction from the subject's actions on objects, particularly from the coordination between these actions. The particular function of reflective abstraction is abstracting properties of an individual's action coordination. That is, reflective abstraction is a mechanism for the isolation of specific properties of a mathematical structure that allows the individual to construct new pieces of knowledge. Taking Piaget's reflective abstraction as a point of departure, Dubinsky and his colleagues (Dubinsky, 1991; Cottrill et al., 1996; Arnon et al., 2014) developed the APOS theory describing the construction of concepts through the encapsulation of processes. Similar to encapsulation is reification – the central tenet of Sfard's (1991) framework emphasizing the cognitive process of forming a (structural) concept from an (operational) process. In the same way, Gray and Tall (1994) described this issue as an overall progression from procedural thinking to proceptual thinking, whereas proceptual thinking means the ability to flexibly manipulate a mathematical symbol as both a process and a concept. Gray and Tall (1994) termed symbols that may be regarded as being a pivot between a process to compute or manipulate and a concept that may be thought of as a manipulable entity as procepts.

Scheiner (2016) revealed that the literature shows an unyielding bias toward *abstraction from actions* as the driving form of abstraction in knowing and learning advanced mathematics. This almost always exclusive view arises directly from the trajectory of our field's history; originating in Piaget's assumption that only reflective abstraction can be the source of any genuinely new construction of knowledge. While abstraction-on-actions

approaches have served many purposes quite well, they cannot track detail of students' knowing and learning processes compatible with the strategy of giving meaning. The recently evolving framework of structural abstraction has attracted attention as a promising tool to shed light into the complexity of students' knowing and learning processes compatible with their strategy of 'giving meaning'.

The Evolving Framework of Structural Abstraction

The distinction between abstraction from actions and abstraction from objects reflects Tall's (2013) distinction between *operational abstraction* and *structural abstraction*. In contrast to Piaget (1977/2001) who dichotomized these two forms of abstraction, Tall (2013) argued that mathematical thinking emerges in these two forms: operational abstraction focusing on actions on objects and structural abstraction focusing on the properties (or structures) of objects. For instance, the development of geometry in the conceptual embodied world focuses mainly on structural thinking, the operational symbolic world blends both operational and structural thinking as new forms of number are introduced as extensional blends in algebra (see Tall, 2013). Obviously, mathematics education researchers used the term 'structural' in diverse ways, referring, for instance, to structural mathematics of axioms and definitions or to the properties of the structure of objects. In the following discussion, we departure from Scheiner's (2016) understanding of structural abstraction as focusing on "the richness of the particular [that] is embodied not in the concept as such but rather in the objects that falling under the concept [...]. This view gives primacy of meaningful, richly contextualized forms of (mathematical) structure over formal (mathematical) structure" (p. 175). Here we focus the attention to several core assumptions that orient the evolving framework of structural abstraction (see Scheiner, 2016; Scheiner & Pinto, 2016b):

Concretizing through Contextualizing

Structural abstraction takes place on mental objects that, in Frege's (1892a) sense, fall under a particular concept. These objects may be either concrete or abstract. Concreteness and abstractness, however, are not considered as properties of an object but rather as properties of an individual's relatedness to an object in the sense of the richness of a person's representations, interactions, and connections with the object (Wilensky, 1991). From this point of view, rather than moving from the concrete to the abstract, individuals, in fact, begin their understanding of (advanced) mathematical concepts with the abstract (Davydov, 1972/1990). The ascending from the abstract to the concrete requires a *concretizing* process where the mathematical structure is particularized by looking at the object in relation with itself or with other objects that fall under the particular concept. The crucial aspect for concretizing is *contextualizing*, that is, setting the object(s) in different specific contexts. Different contexts may provide various senses (Frege, 1892b) of the concept of observation.

Complementizing through Recontextualizing

The central characteristic of the structural abstraction framework is that while, within the empiricist view, conceptual unity relies on the commonality of elements, it is the interrelatedness of diverse elements that creates unity within the approach of structural abstraction. The process of placing objects into different specific contexts allows specifying essential components. Structural abstraction, then, means attributing the particularized meaningful components of objects to the mathematical concept. Thus, the core of structural abstraction is *complementarity* rather than similarity. The meaning of advanced mathematical concepts is developed by complementizing diverse meaningful components of a variety of

specific objects that have been contextualized and recontextualized in multiple situations. This perspective agrees with van Oers' (1998) view on abstraction as related to recontextualization instead of *decontextualization*.

Complexifying through Complementizing

The structural abstraction framework takes the view that knowledge is a complex system of many kinds of knowledge elements and structures. Complementizing implies a process of restructuring the system of knowledge pieces. These knowledge pieces have been constructed through the above-mentioned process or are already constructed elements coming from other concept images, which are essential for the new concept construction. The cognitive function of structural abstraction is to facilitate the assembly of more complex and compressed knowledge structures. Taking this perspective, we construe structural abstraction as moving *from simple to complex* knowledge structures, a movement with the aim to build coherent and compressed knowledge structures. In Thurston (1990)'s words, when the latter is achieved we "can file it away, recall it quickly and completely when you need it, and use it as just one step in some other mental process." (p. 847). From the structural abstraction perspective, abstraction is acknowledged as a movement across levels of complexity (Scheiner and Pinto, 2014).

Emerging Insights from the Structural Abstraction Framework

In this section, we summarize emerging insights we gained so far by using the evolving framework of structural abstraction retrospectively as a lens through which findings on students' (re-)construction of the limit concept of a sequence were reinterpreted. The study by Pinto (1998) provided the context in which she identified mathematics undergraduates' sense-making strategies of formal mathematics. From a cross-sectional analysis of three pairs of students, two prototypical strategies of making sense could be identified, namely 'extracting meaning' and 'giving meaning':

"Extracting meaning involves working within the content, routinizing it, using it, and building its meaning as a formal construct. *Giving meaning* means taking one's personal concept imagery as a starting point to build new knowledge." (Pinto, 1998, pp. 298-299)

The literature on abstraction from actions provides several accounts of how students construct a mathematical concept compatible with their strategy of 'extracting meaning'.

For instance, dynamic views of the limit of a sequence and the genetic decomposition of the limit concept of a sequence are intensively investigated by Arnon et al.'s (2014) APOS theory to respond to how students may construct the concept through the process of reflective abstraction. To mention a few recent investigations supported by the same theory, and compatible with the strategy of 'extracting meaning', Martinez-Planell, Gonzalez, DiCristina, and Acevedo (2012) focused on students' understanding of series and investigated whether students saw series as a process without an end or as a sequence of partial sums, as stated by definition. They respond how students may construct the concept, by considering a distinction amongst their understandings of the concept of a sequence as a list of numbers or as a function defined in natural numbers (McDonald, Mathews, & Strobel, 2000), and concluded that even after formal training, students often think of sequences and series as an infinite, unending process.

However, there are almost no accounts of how students construct a concept compatible with their strategy of 'giving meaning', and the structural abstraction framework has shown to be enlightening with regard to this. Students who 'give meaning' seem to develop representations of the limit concept from their concept image and use them generically (see Yopp & Ely, 2016) for constructing and reconstructing the concept (see Pinto & Scheiner,

2016). This means, such representations are not always generic in the sense of Mason and Pimm (1984) though they are used as if they were of that nature. Moreover, such representations may be productive in some, though not all contexts, in which they are needed. In spite of the striking differences in the knowledge constructions in each case study, that are made explicit by the nature of the representations construed and their use, the three case studies presented in Pinto (1998) on students' strategy of giving meaning have in common a cohesion in their sense-making and in learning the formal mathematics concept (Pinto & Scheiner, 2016; Scheiner & Pinto, 2014). Pinto and Scheiner (2016) concluded that coherence amongst students' sense-making and their (re-)construction of the formal content had been proven to be a central characteristic of those students who 'give meaning'. This does not mean that the reconstructions a student made are configured in a "satisfactory reconstruction or accommodation" scenario (Vinner, 1991, p. 70); rather, that apart of the learning scenario, a student's sense making is coherent with her or his learning of a mathematical concept.

It is important to note that the evolving framework of structural abstraction is problem driven, that is, addressing the need for bringing light into the complexity of students' knowing and learning processes compatible with their strategy of 'giving meaning', rather than filling a theoretical gap just because it exists. The reinterpretation of empirical data on students' strategies of giving meaning in the light of the theoretical framework of structural abstraction proved to be particularly fruitful – not only to provide deeper insights into the strategy of giving meaning but also as a way to deepen our understanding of the phenomenon of structural abstraction that revealed new theoretical developments (Pinto & Scheiner, 2016; Scheiner & Pinto, 2014). In the following sections, we highlight the main theoretical advancements.

The idea of complementizing meaningful components underlying the structural abstraction framework reflects the idea that whether an individual has 'grasped' the meaning of a mathematical concept is situated in specific contexts where the objects falling under the specific mathematical concept have been placed in. In the case studies revisited, these contexts include the formal mathematics one, where mathematical objects are presented as formal definitions and their properties are deduced through formal proofs. Such a diversity of situated or contextualized meanings supports Skemp's (1986) viewpoint that "the subjective nature of understanding [...] is not [...] an all-or-nothing state" (p. 43). The reanalysis of the data indicates that the object of researchers' observation should be directed to students' *partial constructions* of the limit concept. These partial constructions may be specific and productive to particular contexts but may remain not fully connected and may be unproductive in other contexts (for instance, in making sense of the formal definition). The empirical data show that, in the case of the students who give meaning, several meaningful elements and relations in understanding the limit concept of a sequence are involved, although a few elements are missing (or distorted). However, some students are able to (re-)construct some meaningful components at need by making use of their partial constructions, while others are not able to do so.

Our reanalysis indicates that some students have developed *resources* that enable them to (re-)construct the limit concept of a sequence at need. Scheiner and Pinto (2014) focused on a case where a student developed a generic representation of the limit concept of a sequence that operates well in several, although not all, contexts and situations. This particular representation, however, allows the student to (re-)construct the limit concept in other contexts and situations. The reinterpretation of the data sheds light on the phenomenon that individuals may not 'have' all relevant, meaningful components, but, rather, they may have resources to generate some meaningful components and make sense of the context at need. In

that sense, the ‘completeness’ of the complementizing process cannot ever be taken as absolute.

Several researchers suggested exposing learners to multiple contexts and situations. An important insight from using the structural abstraction framework retrospectively is that exposure to multiple contexts is at least important for particularizing meaningful components: various objects falling under a particular mathematical concept have to be set into different specific contexts in order to make visible the meaningful components or mathematical structure of these objects. In so doing, the objects may be ‘exemplified’ through a variety of representations, in which each representation has the same reference (the mathematical object); however, different representations may express different senses depending on the selected representation system (see Fig. 2).

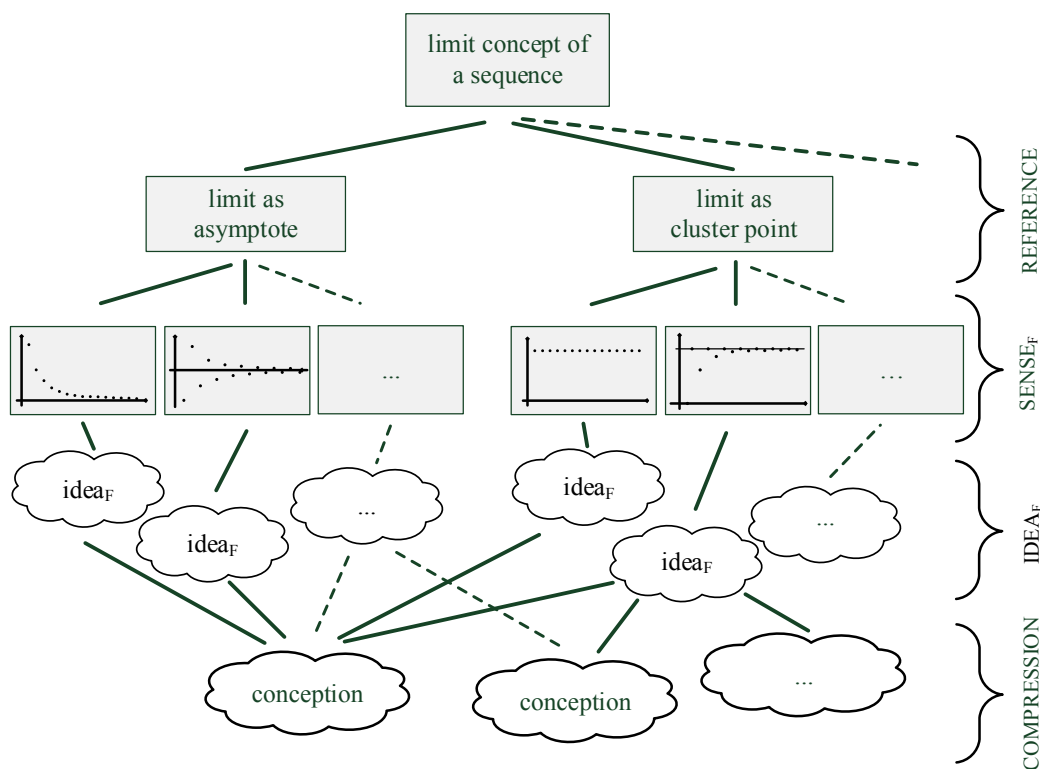

Fig. 2: Reference, sense, and idea

The distinction between *sense* and *reference* has been specified by Frege (1892b) in his work *Über Sinn und Bedeutung*, indicating both the sense and the reference as semantic functions of an expression (a name, sign, or description). In short, the former is the *way* that an expression refers to an object, whereas the latter is the *object* to which the expression refers. According to Frege (1892b), to each representation corresponds a sense; the latter may be connected with an *idea* that can differ within individuals since people might associate different senses with a given representation. Though multiple contexts and situations are needed, a new context that does not provide a new sense will unlikely be productive for concept construction.

Research also indicates that students may have difficulties with the *relationships* between the sense and the reference as well as difficulties in *maintaining* the reference as the sense changes (Duval, 1995, 2006). Thus, one might assume that these difficulties may (at least partly) be overcome by providing students a particular resource (such as a generic

representation of the mathematical concept) that serves as a guiding tool in complementizing the meaningful components indicated in the different senses. From this perspective, a ‘representation for’ is a tool that provides theoretical structure in constructing the meaning of the concept of observation. It necessarily reflects essential aspects of a mathematical concept but can have different manifestations (Van den Heuvel-Panhuizen, 2003). Concerning the learning of the limit concept of a sequence, the reinterpretation of the data indicates that a slightly modified version of a student’s representation (see Fig. 3) may support the complementizing process when the limit concept is recontextualized.

Fig. 3: A generic representation for learning the limit concept of a sequence

Notice that this generic representation for learning the limit concept of a sequence takes account of several students’ common conceptions identified in the research literature, including those as (1) the limit is unreachable, (2) the limit has to be approached monotonically, and (3) the limit is a bound that cannot be crossed (see Cornu, 1991; Davis & Vinner, 1986; Przenioslo, 2004; Tall & Vinner, 1981; Williams, 1991).

The reanalysis of the empirical data gained from Pinto’s (1998) study has shown that students who gave meaning built a representation of the concept and, at the same time, used it as a representation for recognizing and building up knowledge – the reconstruction of the formal concept definition, for instance. The analysis shows that these students consistently used *representations of* mathematical objects to create pieces of knowledge; or, in other words, the representations were actively taken as *representations for* emerging new knowledge and making sense of the context and situation. This shift from constituting a representation of the limit concept to using this representation as a representation for (re-)constructing the limit concept in other contexts can be described in terms of shifting from a *model of* to a *model for* (Streefland, 1985) – a shift from an *after-image* of a piece of given reality to a *pre-image* for a piece of reality to be created. Adopting this view, we may indicate variations in knowledge structures related to the possible explanations that are considered. Models may involve acceptance of other hypothesis through deduction, causality or analogy.

This mental shift from ‘after-image’ to ‘pre-image’ indicates a degree of awareness of the meaningful components and the complexity of knowledge structure that allows the transition from a ‘representation of’ as a result of various representations expressing specific objects set in different contexts to a ‘representation for’ constructing and reconstructing the limit concept, if inter alia, in formal mathematical reasoning. We suggest that a generic representation, as presented in Fig. 3, may provide an instructional tool that supports raising the awareness of meaningful components in learning the limit concept of a sequence. In other

words, such a generic representation may direct students' perception of meaningful components although it does not enshrine mathematical knowledge.
